## Electro-magnetic transient surveys: A key to progress in High Energy v astronomy

Eli Waxman Weizmann Institute of Science

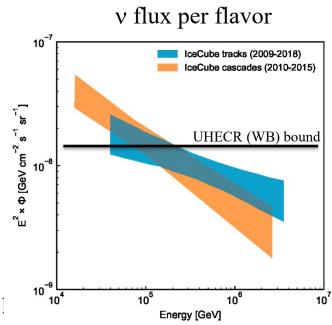

### IceCube's extra-Galactic v's: What we have learned

#### $\sim 50 \text{ TeV} - \sim 3 \text{ PeV}$

- The energy production rate density in the local universe in  $\sim 100$  TeV v's and in  $> 10^{10}$  GeV CRs is similar:  $\sim 10^{44}$ erg/Mpc<sup>3</sup>yr ( $\Phi \approx \Phi_{WB}$ ): Suggests that
  - v's and HE CRs produced by the same sources;
  - HE CR sources reside in "calorimetric" environments, most likely star-forming galaxies, where 1(E/Z) PeV CRs lose all their energy to pion
- No "point sources" (multiple event sources) identified. Flux dominated by many weak sources:  $n_s > 10^{-7}/Mpc^3$ ,  $L_v < 10^{42.5}$  erg/s.

#### $\sim 20 \; TeV$

•  $\Phi \approx 2\Phi_{WB}$  and is in tension with the 100 GeV  $\gamma$  background. Suggests the existence of "hidden sources", from which only (mainly) v's escape.

## The key goals of HE v astronomy

- Identify the sources of (very) HE cosmic-rays,
- Provide unique constraints on models of HE astrophysical sources,
- Possibly: Study v/fundamental physics.

The detection of high energy (HE) extra-Galactic neutrinos by IceCube demonstrates the potential for achieving these goals.

Fulfilling the potential relies on the electromagnetic identification of the neutrino sources.

## Extra-Galactic v's: What we are missing

#### 10 TeV - 10 PeV

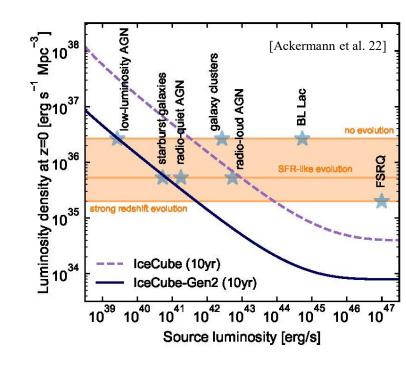

- The sources have not been identified.
  - Indication (<3σ) for an association with one blazar, and one SFR/AGN galaxy. [Blazar association, Buson et al. 22- caveats & inconsistencies remaining.]
  - Blazars may contribute to, but cannot dominate, the flux.
- The spectrum measurement is crude.
  - A single power-law or multiple "breaks"?
- The flavor ratio measurement is crude.
  - Consistent with 1:1:1.

#### $10^8 - 10^{10} \, GeV$

• A flux measurement (10<sup>-9</sup>GeV/cm<sup>2</sup>s sr) will constrain the UHE CR composition.

## Identifying the sources: An order of magnitude increase in the detected v number is required

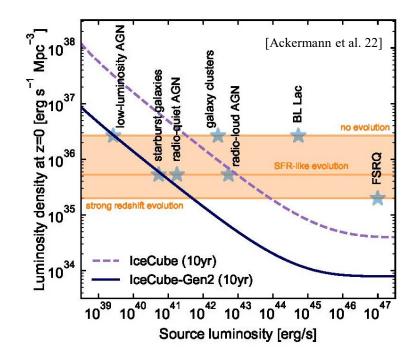

- Measured flux implies a (z=0) luminosity density  $n_s L_v \approx 10^{43.5} \text{erg/Mpc}^3 \text{yr} = 10^{36} \text{erg/Mpc}^3 \text{s}$ .
- $N(\text{multiple tracks}) = 1 \left(\frac{\zeta}{3}\right)^{-\frac{3}{2}} \left(\frac{n_S}{10^{-7} \text{Mpc}^{-3}}\right)^{-\frac{1}{2}} \left(\frac{A}{1 \text{km}^2}\right)^{\frac{3}{2}}$   $\Rightarrow n_S > \frac{10^{-7}}{\text{Mpc}^3} \left(\frac{A}{1 \text{km}^2}\right)^3, \ L_{\nu} < 10^{42.5} \text{erg/s},$   $N(\text{all sky}) > 10^6.$
- Rare bright sources (eg "blazars")- Ruled out as the dominant sources.

An order of mag increase in sensitivity is required to detect multiple events from nearby sources with  $n_s \sim 10^{-5}/\text{Mpc}^3$  (eg starbursts).

## Identifying the sources: An order of magnitude increase in the detected v number is required

- Measured flux implies a (z=0) luminosity density  $n_s L_v \approx 10^{43.5} \text{erg/Mpc}^3 \text{yr} = 10^{36} \text{erg/Mpc}^3 \text{s}$ .
- $N(\text{multiple tracks}) = 1 \left(\frac{\zeta}{3}\right)^{-\frac{3}{2}} \left(\frac{n_s}{10^{-7} \text{Mpc}^{-3}}\right)^{-\frac{1}{2}} \left(\frac{A}{1 \text{km}^2}\right)^{\frac{3}{2}}$   $\Rightarrow n_s > \frac{10^{-7}}{\text{Mpc}^3} \left(\frac{A}{1 \text{km}^2}\right)^3, \ L_{\nu} < 10^{42.5} \text{erg/s},$   $N(\text{all sky}) > 10^6.$
- Rare bright sources (eg "blazars")- Ruled out as the dominant sources.

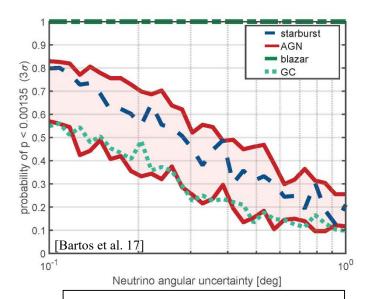

An order of mag increase in sensitivity is required to detect multiple events from nearby sources with  $n_s \sim 10^{-5}/Mpc^3$  (eg starbursts).

Can we make progress towards source identification before this is achieved (in  $\sim 2040$ )?

## Source identification by angular correlation with EM source catalogs: Unlikely.

- v track direction uncertainty ~ 1 deg,
   50% of v's produced beyond z≈ 1, d<sub>L</sub> ≈ 5 Gpc,
   >>1 sources/deg<sup>2</sup>.
- Can we look only at nearby sources, with lower angular sky density?
  - $\approx$ 5% of v's produced by sources at d<0.5 Gpc
    - → Only a handful of track events from d<0.5 Gpc sources.</p>
  - Catalogs are highly incomplete already at 0.2 Gpc.

Probability for a 3σ detection, for 10 yrs IceCubeGen2, and complete catalogs to 0.2 Gpc

- Coincident transient v/EM detection increases the significance of an angular association, for transient duration Δt << T ~ 1yr.</li>
   (Δt~ months- minor improvement.)
- The absence of neutrino point sources:

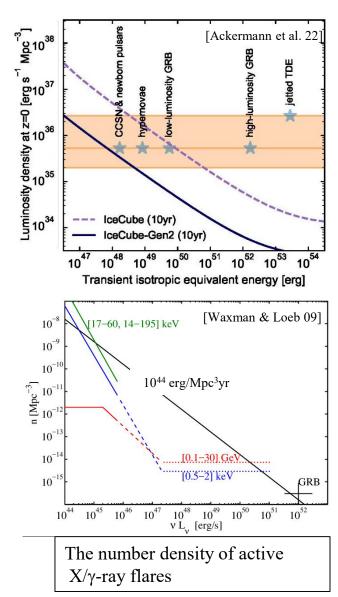

$$\dot{n}_{\rm S} = \frac{n_{\rm S}}{T} > \frac{10^{-7}}{{
m Mpc^3yr}}, \ E_{\nu} = L_{\nu} T < 10^{50} {
m erg}.$$

The number of active  $X/\gamma$ -ray flares:

$$L_{\gamma} < 10^{45} \text{erg/s} \text{ (assuming } L_{\gamma} \leq L_{\gamma} \text{)}.$$

The required sensitivity:

$$f_{\gamma} < \frac{10^{44} \text{ erg/s}}{4\pi (1\text{Gpc})^2} = 10^{-12} \text{ erg/cm}^2 \text{s}.$$

- Coincident transient v/EM detection increases the significance of an angular association, for transient duration Δt << T ~ 1yr.</li>
   (Δt~ months- minor improvement.)
- The absence of neutrino point sources:

$$\dot{n}_s = \frac{n_s}{T} > \frac{10^{-7}}{\text{Mpc}^3 \text{yr}}, \ E_v = L_v T < 10^{50} \text{erg}.$$

The number of active  $X/\gamma$ -ray flares:

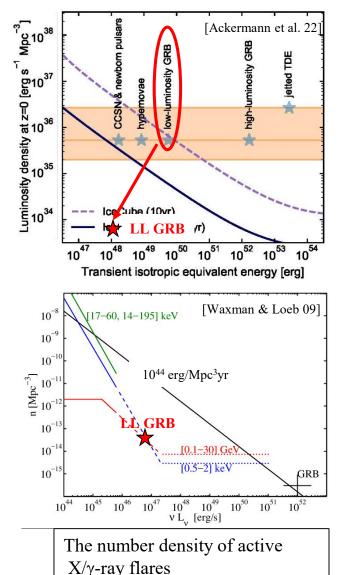

$$L_{\gamma} < 10^{45} \text{erg/s} \text{ (assuming } L_{\gamma} \leq L_{\gamma} \text{)}.$$

The required sensitivity:

$$f_{\gamma} < \frac{10^{44} \text{ erg/s}}{4\pi (1\text{Gpc})^2} = 10^{-12} \text{ erg/cm}^2 \text{s}.$$

For LL GRBs to produce the observed  $\nu$  flux, they need to produced 100 times more energy in  $\nu$ 's than in  $\gamma$ 's.

This is not supported by any observation.

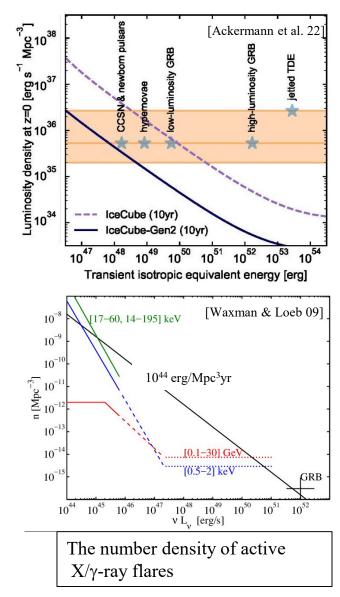

• The required sensitivity:

$$f_{\gamma} < \frac{10^{44} \text{ erg/s}}{4\pi (1\text{Gpc})^2} = 10^{-12} \text{ erg/cm}^2 \text{s}.$$

- $\Delta t < 1 \text{ min} \text{Requires very wide FOV EM detectors for simultaneous observations.}$ 
  - BAT/GBM ~1 MeV sensitivity ~  $10^{-8.5}$  erg/cm<sup>2</sup>s, corresponding to  $10^{48}$ erg/s at 1 Gpc.
    - → Far from required sensitivity.
  - Fermi LAT ~1GeV sensitivity
    - $\sim 10^{-12}$  erg/cm<sup>2</sup>s for 1yr integration.

LHAASO sub TeV ( $\tau_{\gamma\gamma}$ =1 for 0.3 TeV @ 1Gpc) sensitivity ~ 10<sup>-11</sup> erg/cm<sup>2</sup>s for 1yr integration.

→ Far from required sensitivity.

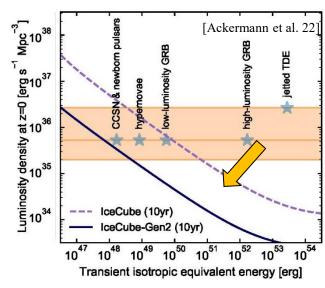

• The required sensitivity:

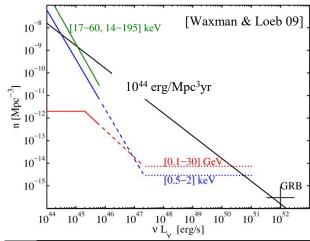

$$f_{\gamma} < \frac{10^{44} \text{ erg/s}}{4\pi (1\text{Gpc})^2} = 10^{-12} \text{ erg/cm}^2 \text{s}.$$

- $\Delta t < 1 \text{ min} \text{Requires very wide FOV EM detectors for simultaneous observations.}$ 
  - BAT/GBM ~1MeV sensitivity ~  $10^{-8.5}$  erg/cm<sup>2</sup>s, corresponding to  $10^{48}$ erg/s at 1 Gpc.
    - → Far from required sensitivity.
  - Fermi LAT ~1GeV sensitivity
    - $\sim 10^{-12}$  erg/cm<sup>2</sup>s for 1yr integration.

LHAASO sub TeV ( $\tau_{\gamma\gamma}$ =1 for 0.3 TeV @ 1Gpc) sensitivity ~ 10<sup>-11</sup> erg/cm<sup>2</sup>s for 1yr integration.

- → Far from required sensitivity.
- Very bright transients, GRBs/TDE-jets, may be detectable.
   However, they contribute up to ~1% of the flux,
   i.e., up to ~1 v.

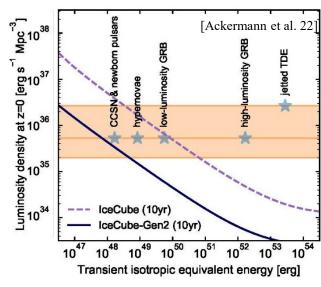

The number density of active  $X/\gamma$ -ray flares

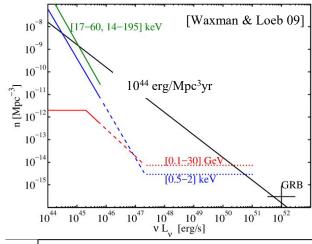

# Can the sources be identified by temporal correlation with $X/\gamma$ -ray flares? Possibly in X-rays, if bright.

• The required sensitivity:

$$f_{\gamma} < \frac{10^{44} \text{ erg/s}}{4\pi (1\text{Gpc})^2} = 10^{-12} \text{ erg/cm}^2 \text{s}.$$

- $\Delta t \sim 1 \text{ hr -1 d: Allows slewing } \sim 1 \text{deg FOV detectors.}$ 
  - XRT ~1keV 3hr sensitivity ~ 10<sup>-13</sup> erg/cm<sup>2</sup>s,
    → A few transients may be detected, if bright enough.
    (NuStar FOV 10').
  - CTA (sub-TeV) 50 hr sensitivity ~ 10<sup>-12</sup> erg/cm<sup>2</sup>s,
     → Marginal.
     (HESS/MAGIC less sensitive).

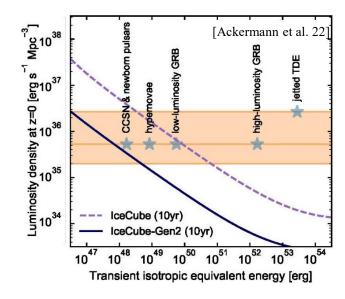

The number density of active  $X/\gamma$ -ray flares

## Can UV/Optical transient surveys help identify the sources? Possibly.

- Δt < 1 min Requires very wide FOV EM detectors.</li>
   Not sensitive enough.
- Δt ~ 1 hr -1 d: Allows slewing.
   Requirements:
  - FOV  $> 1 \text{ deg}^2$ ,
  - Sensitivity much better than 10<sup>-13</sup> erg/cm<sup>2</sup>s.

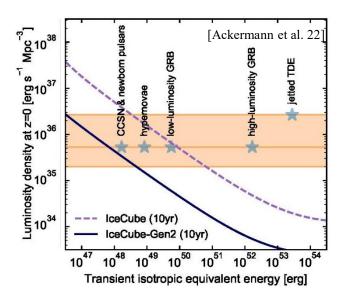

SWIFT UVOT  $-0.1 \text{ deg}^2$ ,  $5x10^{-15} \text{ erg/cm}^2\text{s}$  (10<sup>4</sup>s).

## Can UV/Optical transient surveys help identify the sources? Possibly.

- Δt < 1 min Requires very wide FOV EM detectors.</li>
   Not sensitive enough.
- Δt ~ 1 hr -1 d: Allows slewing.
   Requirements:
  - FOV  $> 1 \text{ deg}^2$ ,
  - Sensitivity much better than 10<sup>-13</sup> erg/cm<sup>2</sup>s.

SWIFT UVOT  $-0.1 \text{ deg}^2$ ,  $5x10^{-15} \text{ erg/cm}^2\text{s}$  (10<sup>4</sup>s).

- Many candidate sources are expected to be UV bright.
  - Supernovae: Jet driven explosions,

(LL GRBs),

Ejecta – Circumstellar Medium interaction,

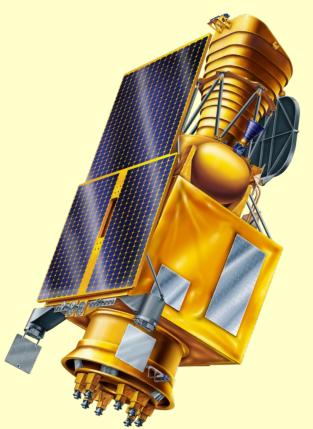

- Tidal disruption events.

A handful of v- $\gamma$  associations for the nearest, yet quite distant – 0.5 Gpc, sources, will not enable a systematic detection and study of the transient sources.

Sensitive wide FOV UV/Optical surveys are key for systematic study and understanding.

## **ULTRASAT: A Wide-Field UV Space Telescope**

### Revolutionize our understanding of the hot transient Universe

# The study of Transient Cosmic Phenomena is taking Center Stage

An exciting frontier, many fundamental open questions

Sources	Open questions
Gravitational Wave sources NS-NS/BH mergers	<ul> <li>Physics of the sources of gravitational waves</li> <li>Where did the heavy elements, Fe – U, form?</li> <li>Current H<sub>0</sub></li> </ul>
Supernovae	- How do massive stars explode and affect their environment?
Tidal disruption of stars (TDE) by super-massive black holes (SMBH)	<ul><li>What is the SMBH "demographics"?</li><li>How do they affect their environment?</li><li>How is mass accreted onto BH?</li></ul>
•••	•••

## Why now?

Technology enables telescopes with very large fields of view, Crucial for "catching" transient events.

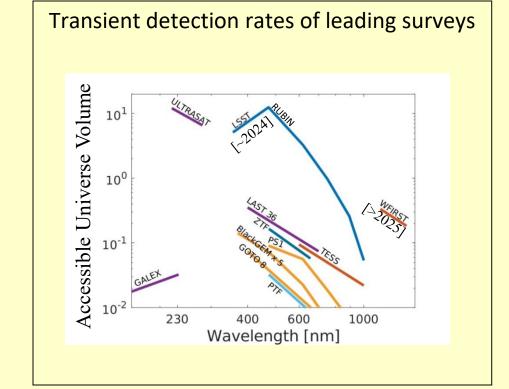

## **ULTRASAT's uniqueness**

#### **Key Properties**

- Very large, 200 deg<sup>2</sup>, field of view.
- High UV (230-290nm) sensitivity:  $1.5 \times 10^{-3} \text{ ph/cm}^2 \text{ s} \quad (900\text{s}, 5\sigma)$  [m = 22.4], $3 \times 10^{-15} \text{ erg/cm}^2 \text{ s} \quad (10^4\text{s}).$

#### **Key Capabilities**

- Monitor an unprecedentedly large volume of the Universe.
- New window in wavelength (NUV) and in cadence (minutes - months).

- Real-time alerts to ground/space-based telescopes (GEO orbit), initiate world-wide follow-ups.
- ToO: Instantaneous >50% of the sky in <15 min for >3 hr.

## **ULTRASAT: Key Science Goals**

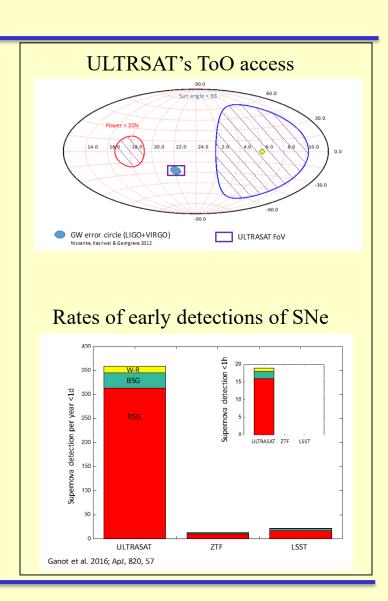

#### EM counterparts to GW sources

Starting (late) 2025: GW detectors will identify ~10 NS-NS events/yr, ~100 deg<sup>2</sup> error box.

- Fast localization of NS-NS/BH mergers: Rapid, <15min, access to >50% of sky, Cover GW error box in a single image.
- Localize mergers to their host galaxies.
- Provide UV light curves to measure ejecta properties.

#### Deaths of massive stars

- High quality early high cadence UV data,
   Rapid alerts for follow-ups,
   100's of SNe including rare types.
- Measure properties of supernova progenitors.
- Map progenitors to supernova types.
- Reveal pre-explosion evolution and mass loss.

	All Sky Survey – galaxies	>108	Galaxy Evolution, star formation rate			

## **ULTRASAT: Implementation & Collaboration**

Spacecraft: IAI

Telescope: Elop/Elbit

Focal Plane Array
DESY/Helmholtz
(Germany)

Sensor: Tower (Israel)

Hosted launch to GTO: NASA

(MoU negotiations near final stage)

Launch Q2/3 2025

>3.5 year science mission (6 year fuel)

Dimentions:  $1.5 \times 1.7 \times 3.4 \text{ (m}^3\text{)}$ 

Power: 500 W

Ø 670 mm

Mass: 500 + 630 (Prop) kg

### **ULTRASAT: Status & Timeline**

- The program is on track.
- Full teams have been assigned and are working.
- Major risks identified and managed:
  - Challenging time line,
  - Complex Interfaces,
  - Contamination prevention and control.
- Mission cost (including launch) approx.
   \$110M.

Mile Stone	ARO + Month	Time
Kick off	0 (23 September 2019)	"Q4" 2019
SRR	3	Q1 2020
SDR	6	Q2 2020
PDR	17	Q1 2021
CDR	27	Q4 2021/ Q1 2022
Supply of FPA ("camera")	46	Q3 2023
Supply of Telescope	56	Q2 2024
Satellite ready	66	Q1 2025
Launch	67 -	Q2/3 2025

### **ULTRASAT: Science Collaboration**

- 13 Science Working Groups WG members receive real time data access.
   Open to all (and already including most) Israeli astronomers.
- NASA Launch contribution- MoU negotiations at final stage,
   Science return: US PIs (NASA funded) will join WG's,
   NASA project scientist: J. Rhoads.
- DESY Camera contribution Science return: 3 DESY PIs in WG's.
- Rubin (LSST) collaboration- advanced negotiations.

## **ULTRASAT: Science impact**

- Revolutionize our view of the hot transient Universe:
  - Discovery volume 300 X GALEX,
  - Continuous min-mon cadence at 22.4mag in a new window (NUV),
  - Real-time alerts to ground/space-based telescopes.
- A broad impact:

GW sources, SNe, variable and flare stars, AGN, TDEs, compact objects, galaxies.

Groundbreaking science with an affordable satellite mission.

## **Summary**

- HE  $\nu$  astronomy has the potential to
  - Provide unique constraints on models of HE astrophysical sources, and
  - Identify the sources of (very) HE cosmic-rays.
- Fulfilling the potential relies on the EM identification of the neutrino sources.
- $M_{eff}$ ~10 Gton @  $10^5 10^8$ GeV (IceCube Gen2 + KM3NeT/GVD/P1) is required to
  - Detect multiple events from few nearby sources (eg starbursts),
  - Possibly detect luminous transients (GRB/TDE-jet) contributing ~1% of the flux,
  - Obtain accurate v spectrum, angular distribution and flavor content.
- EM follow-up observations may identify hour-day long transient sources, Crucial for a systematic study of the sources.
  - EM detector requirements:  $FOV > 1 deg^2$ , Sensitivity better than  $10^{-13}$  erg/cm<sup>2</sup>s.
  - May be possible at X-ray (XRT), UV/O.
  - Very challenging at sub-TeV (CTA).
- 10<sup>8</sup> 10<sup>10</sup> GeV: A flux measurement (10<sup>-9</sup>GeV/cm<sup>2</sup>s sr) will constrain the UHE CR composition (Radio).

## Backup Slides

## **Science goal: Planet habitability**

- UV flares and Coronal Mass ejections around prime candidate stars for terrestrial planet searches (M-dwarfs/young Solar analogues)
  - Severely limit habitability,
  - May allow prebiotic chemistry,
  - May produce false positive biomarker signatures (O<sub>3</sub> from photo-dissociation of H<sub>2</sub>O & CO<sub>2</sub>).
- Flares dominate UV output. Flare rates unknown.
- ULTRASAT will monitor ~10<sup>6</sup> stars
  - Determine NUV flare frequency and luminosity distribution as functions of both spectral subclass and stellar rotation period,
  - Determine best habitable planet candidates (e.g., from TESS) for expensive spectroscopic bio-marker searches, e.g. by JWST (extended).

## **ULTRASAT: Mission profile**

#### ALL SKY SURVEY

- 3hr/day during the first 6 months
- 7x deeper than state-of-the art (GALEX) (23 AB limiting mag @ |b|>30°)

#### LONG STARES

- 2 directions near the Ecliptic poles, minimize Galactic extinction and zodiac bgnd
- Real-time data download and analysis
- Alerts within 15min of observations
- 10% of time lower cadence (8000 sq. deg., 4day)- see Eran's talk
- Targets of Opportunity (ToO's)
  - Instantaneous >50% of the sky in <15 min for >3 h
  - No limit on ToO number, except for max 75 with negative power balance (~25%)
  - Continuous transmission to the ground

### Focal Plane array: Main characteristics

- BSI CMOS from Tower Semiconductors
   (4 tiles aligned to < 50 μm)</li>
- High UV QE using high-K dielectric coating, optimized anti-reflection coating
- AnalogValue electronics design, Ramon Space support for space qualified design (e.g., radiation hardness)

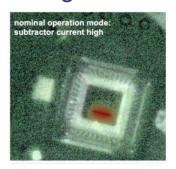

#### Sensor main Specs.

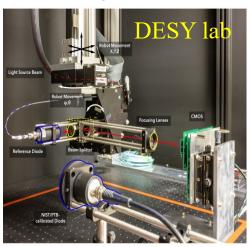

Photosensitive surface	90x90 mm
Pixel size	9.5 µm
Operation waveband	230-290nm
Mean QE in Operation band	>70%
Operation temperature	200±5 °K
Dark current @ 200 °K	<0.03 e <sup>-</sup> /sec
Readout mode	Rolling shutter
Readout time	<25 sec
Readout noise @ High-gain	<3.5 e <sup>-</sup> /pixel
Electronic cross-Talk	<0.01%
Pixel sampling scheme	HDR capability
Low-gain Well capacity	140-155 Ke <sup>-</sup>
High-gain Well capacity	16-21 Ke⁻
Bits per Pixel – total (data only)	14 (13)
Pixel sampling scheme  Low-gain Well capacity  High-gain Well capacity	HDR capability 140-155 Ke <sup>-</sup> 16-21 Ke <sup>-</sup>

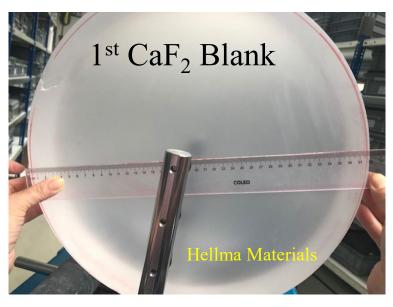

### Long lead items (LLI)

## CMOS detectors produced by Tower, being tested in Germany

#### First lens blanck

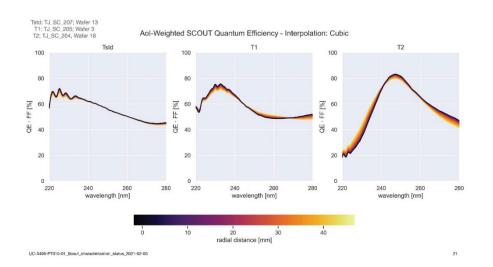

### Key technology challenges

• CMOS sensor - UV QE>60% (Tower).

 UV optics performance across a wide FOV (WIS/Elop).
