

GEM signals analysis

From deconvolved APV test-beam data to TIGER response

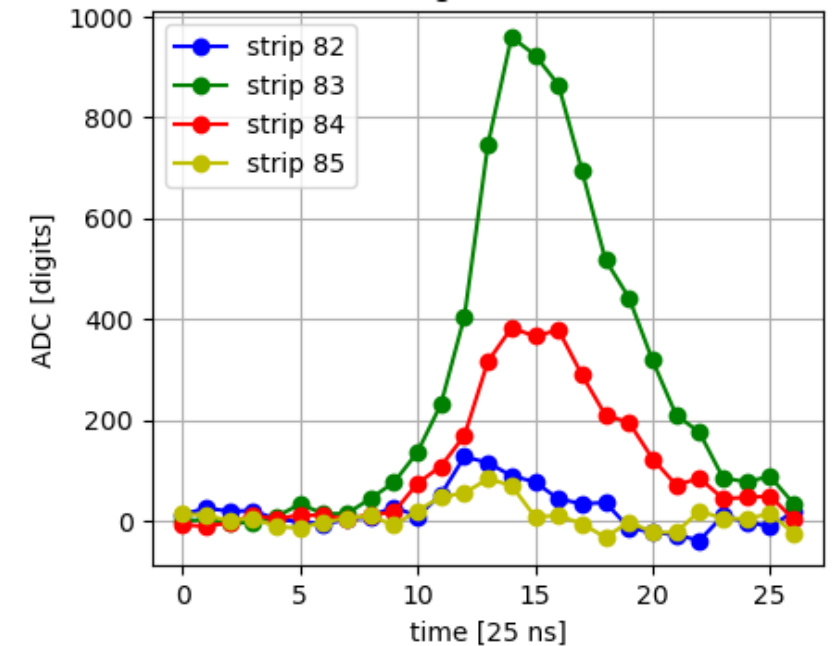

Fabio Cossio

BESIII Italia Meeting

07.04.2022

Motivation and methods

- APV/SRS provides 27 digitized samples of the amplified APV output signal with a time bin of 25ns. From this information it is possible to apply a deconvolution and thus extract the induced GEM signals with a good approximation.
- Use test-beam data, taken with APV/SRS system and planar GEMs, to extract some more detailed information about the GEM signals (duration, shape, amplitude) with a CGEM-IT-like configuration (5mm drift gap, Ar-ISO gas mixture)
- Use these signals to study the response of TIGER electronics and look for some possible optimization of TIGER configuration parameters (*integ_time*) or hints for data analysis

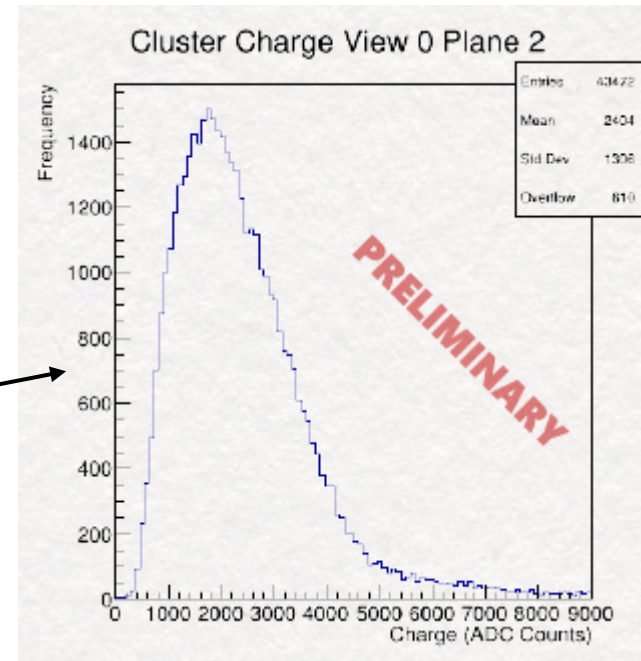

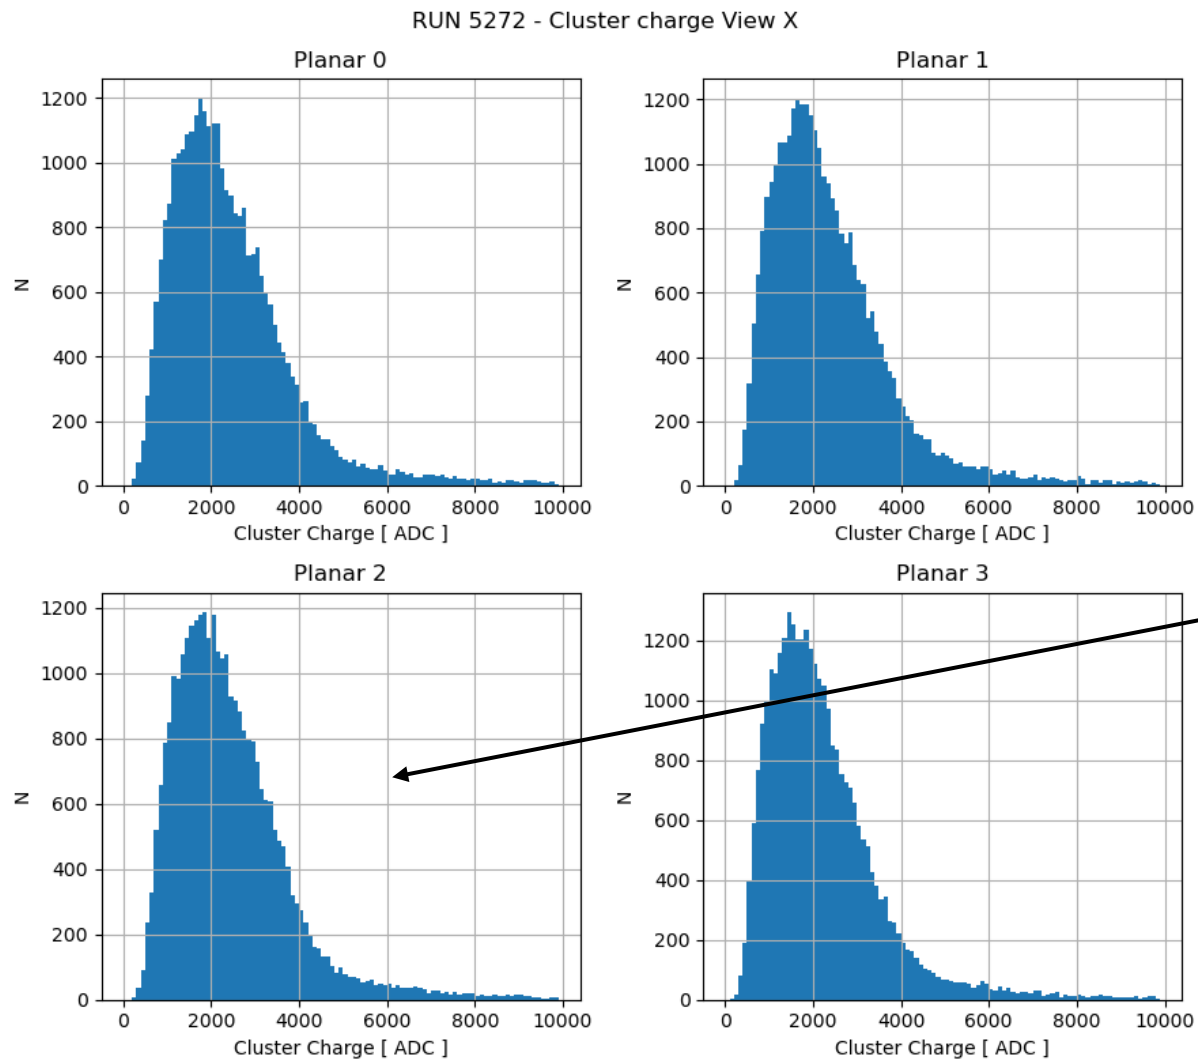

CERN – NA H4 beam line, July 2021

Dataset selection

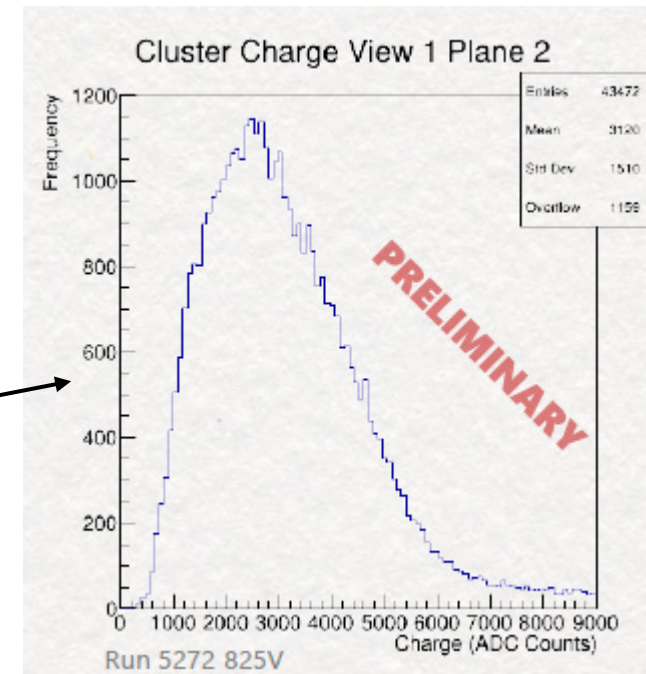

- RUN
 - **5272 (HV = 825 V, angle = 0°)**
 - 5275 (HV = 835 V, angle = 45° on X-view strips)
 - 5271, 5273, 5265, 5267 also available but not shown in this talk
- Selections
 - Select higher charge cluster for each view
 - No more than one cluster with 1000 ADC cluster charge
 - At least 1 cluster for each view and planar
 - Cut events if cluster on planar 3 view-X has strips in range 0-32
 - Cut events if cluster has strips in range 0-1
 - Cut events if cluster has strips in range 126-127
- 31k events after these selections for RUN 5272 (100k triggers)

APV model

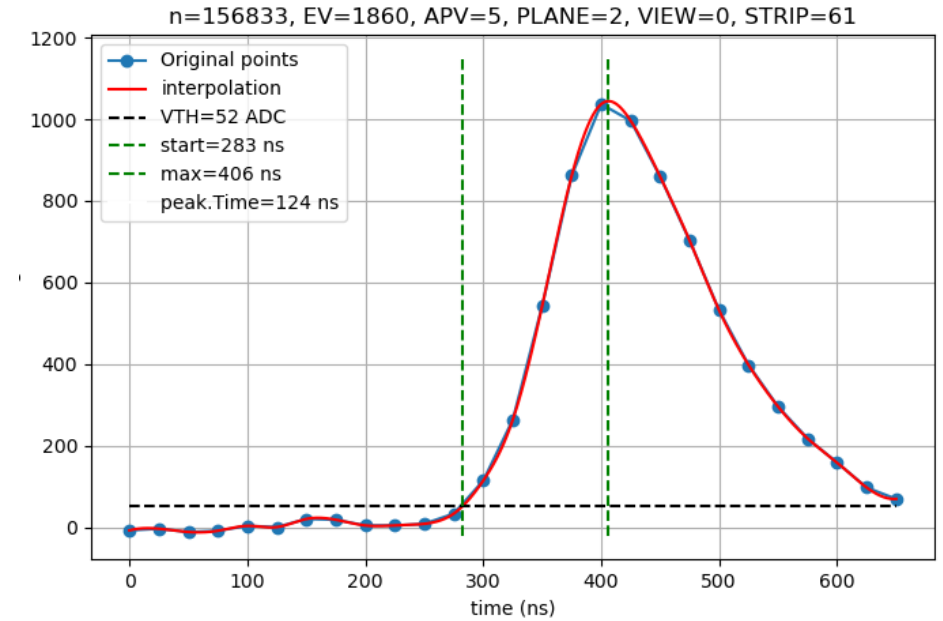

Transfer function: CR-RC shaper with
50 ns peaking time

Signal deconvolution

- Clean noisy points before and after the signal (not always possible)
- Interpolate 25ns points to increase granularity of the curve to be deconvolved and apply filter to reduce large fast oscillations

Signal deconvolution

- Deconvolve using APV transfer function

$$X(s) = \mathcal{L}\{x(t)\}$$

$$Y(s) = \mathcal{L}\{y(t)\}$$

$$Y(s) = H(s) X(s)$$

$x(t)$ = APV input (GEM signal)

$y(t)$ = APV output (ADC codes)

$H(s)$ = APV transfer function

- Re-convolve to check goodness of procedure

Signal deconvolution

- From deconvoluted input extract signal duration and charge
- Signal duration taken as 5%-95% integrated charge time interval

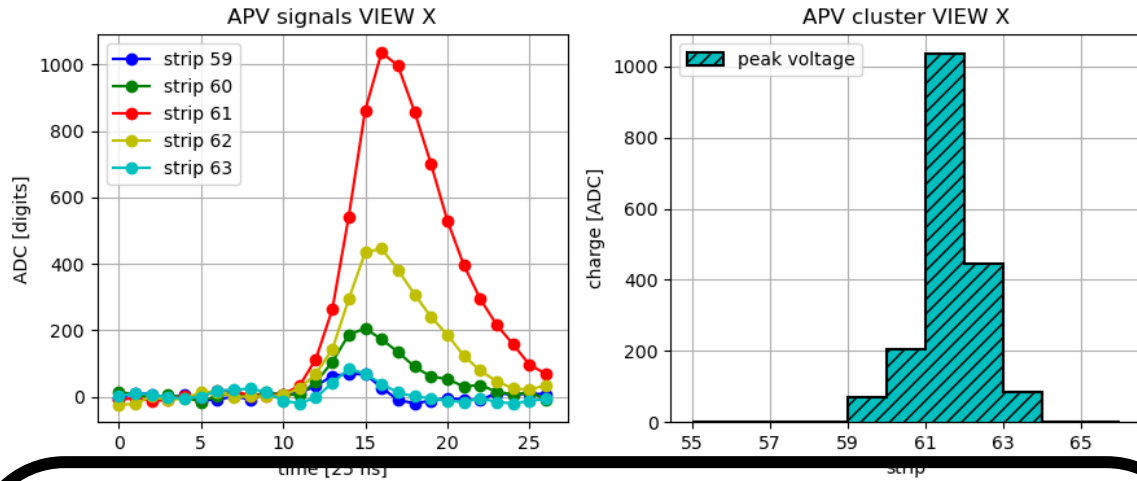

RUN 5272, Event 1860, Planar 2, View 0, Strip 61

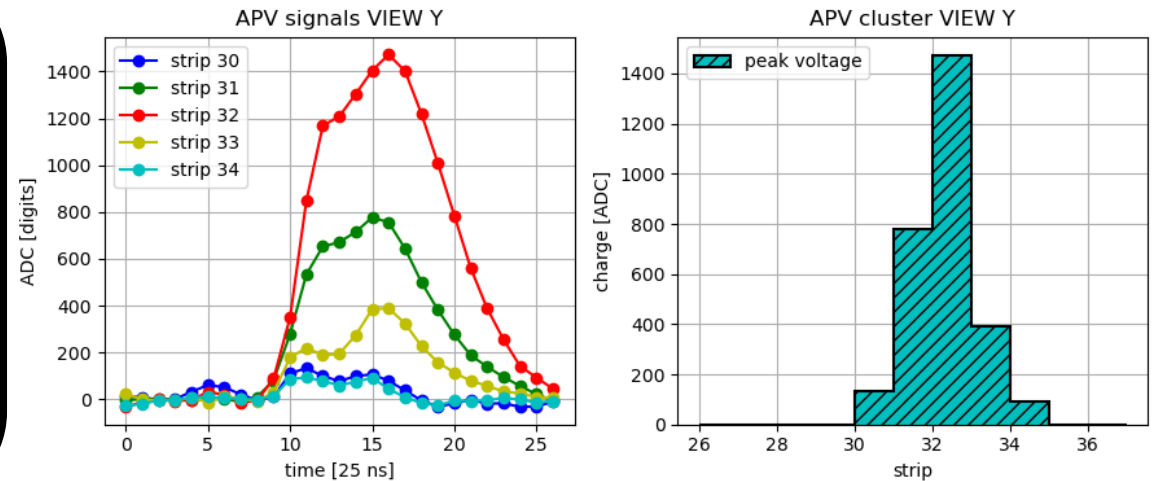

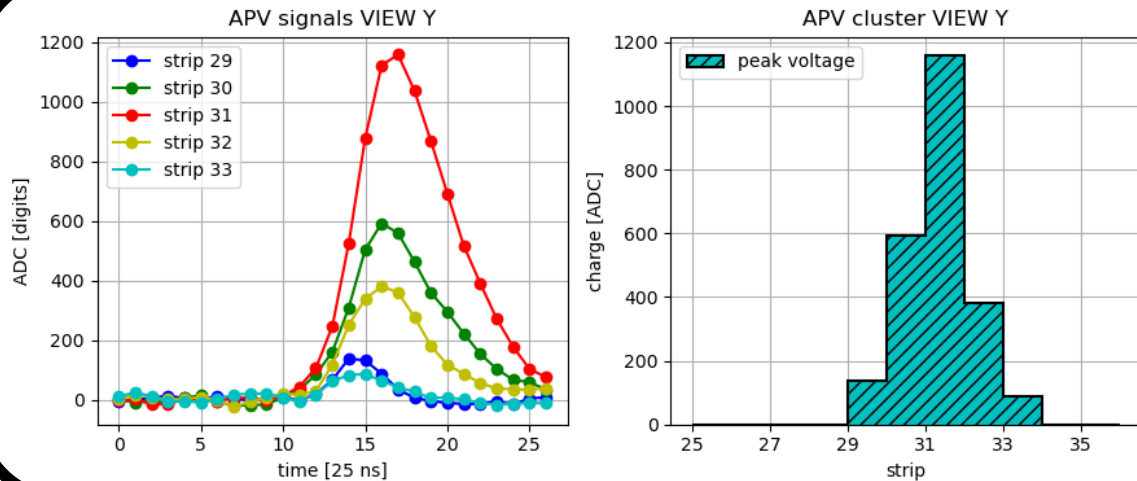

Single signal analysis

Look at one event

RUN = 5272, Planar 2, Event 1860

RUN = 5272, Planar 3, Event 1860

Look at one cluster (strip 29-33)

RUN 5272, Event 1860, Planar 2, View 1, Strip 29

RUN 5272, Event 1860, Planar 2, View 1, Strip 30

Look at one cluster (strip 29-33)

Look at one cluster (strip 29-33)

- Strips with high charge seem to have longer duration signals
- Strips in the tails of cluster (low charge) seem to have shorter duration signals
 - These strips don't see the full 5mm drift gap signal?
 - Capacitive effects?
- Let's apply some of these signals to TIGER

APV (1)

Input signal

- long duration: 140-150 ns
- charge: 44 fC

APV output signal

- peaking time of 124 ns vs 50 ns expected from delta input current

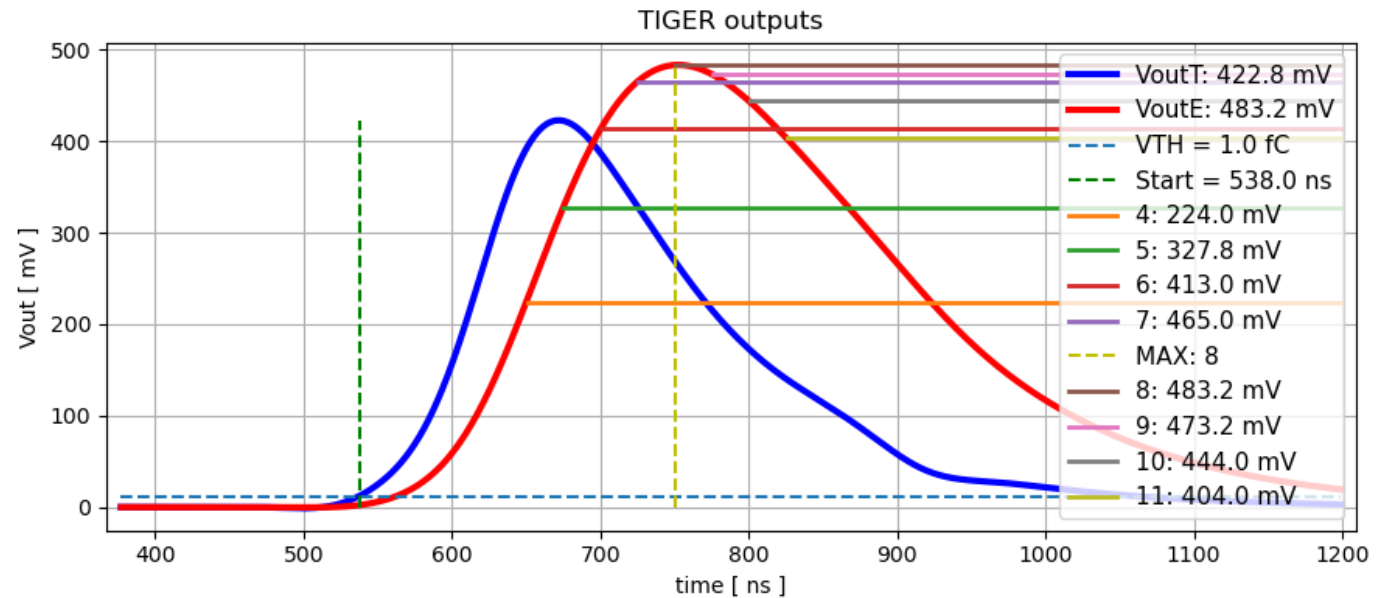

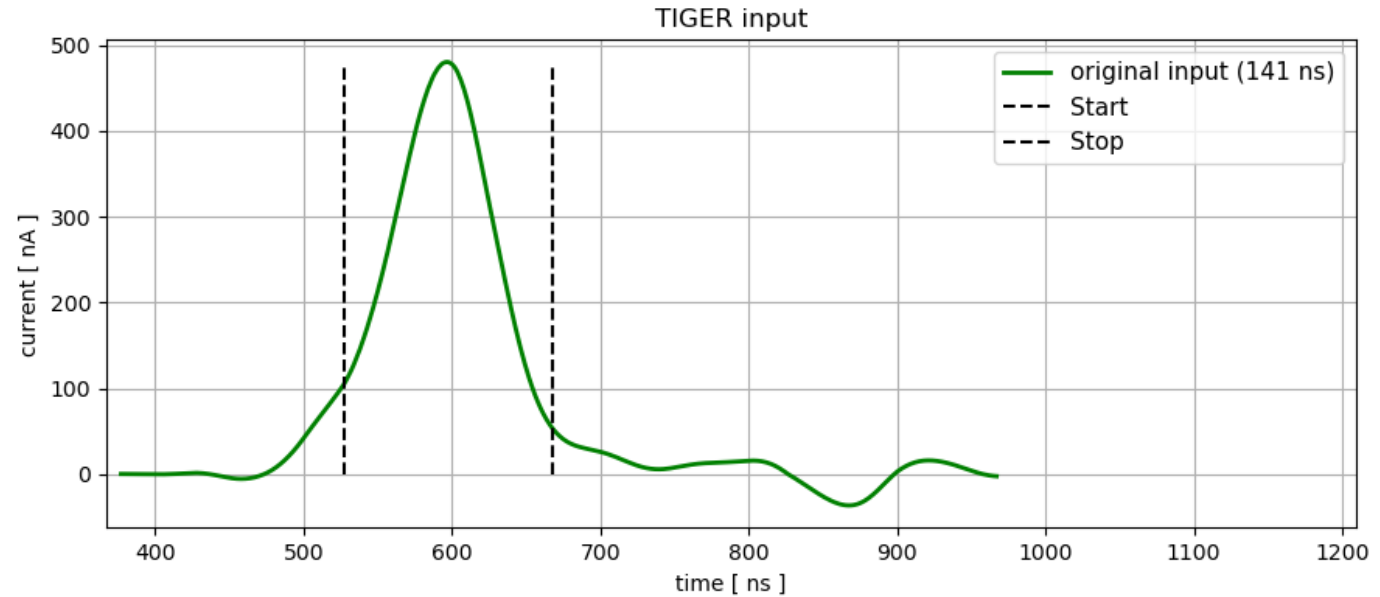

RUN 5272, Event 1860, Planar 2, View 0, Strip 61

TIGER (1)

- Peak voltage = 483 mV
- $Q = 40 \text{ fC}$ (3-4 fC of ballistic deficit)
- MAX at $integ_time = 8$

- Sampled voltage @ $integ_time = 6$
 - 413 mV → $Q = 34 \text{ fC}$

APV (2)

Input signal

- long duration: 180-190 ns
- charge: 25 fC

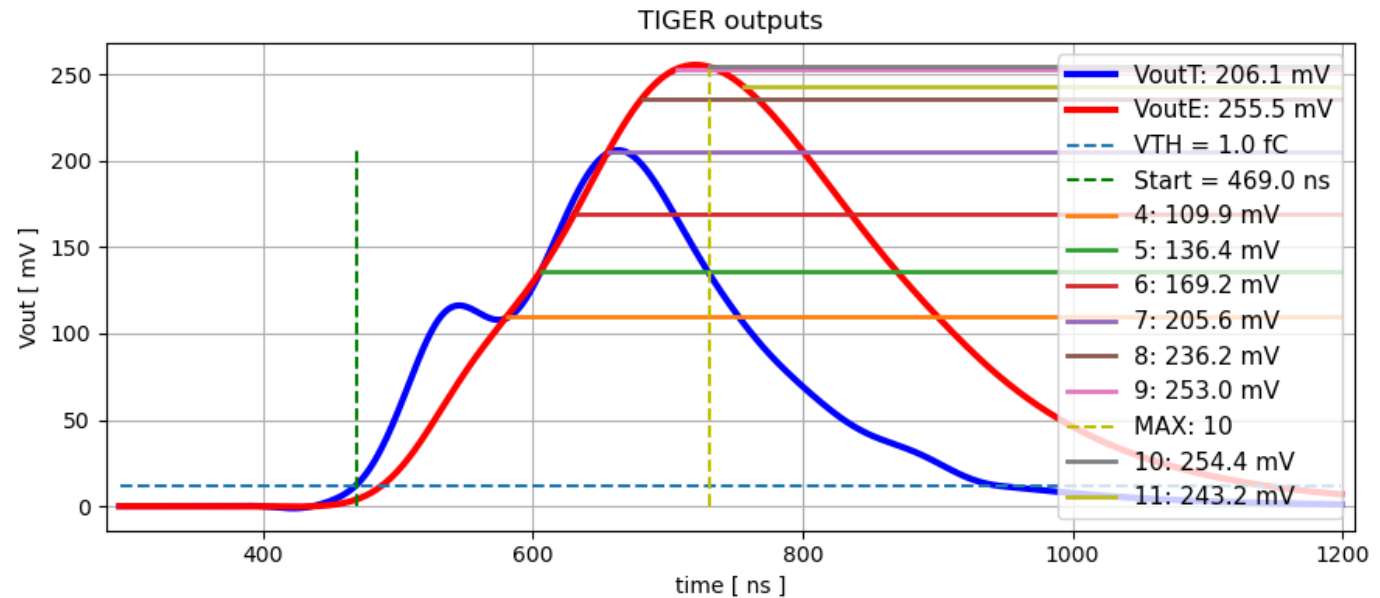

APV output signal

- peaking time of 200 ns vs 50 ns expected from delta input current

TIGER (2)

- Peak voltage = 255 mV
 - $Q = 21 \text{ fC}$ (4 fC of ballistic deficit)
 - MAX at $integ_time = 10$
-
- Sampled voltage @ $integ_time = 6$
 - 169 mV → $Q = 14 \text{ fC}$

APV (3)

Input signal

- short duration: 70 ns
- charge: 32 fC

APV output signal

- peaking time of 80 ns vs 50 ns expected from delta input current

RUN 5272, Event 5963, Planar 0, View 1, Strip 111

TIGER (3)

- MAX at $integ_time = 6$
 - Peak sampled voltage = 375 mV
 - $Q = 31$ fC (<1 fC of ballistic deficit)
-
- Sampled voltage @ $integ_time = 6$ is OK
 - Sampled voltage @ $integ_time = 9$ is 304 mV $\rightarrow Q = 25$ fC (20% of signal is lost)

Full RUN analysis

Deconvoluted signal width (RUN 5272)

- $v_d = 38 \text{ um/ns}$
- Induction gap = 2 mm
- Drift gap = 5 mm

- Induction time = 53 ns
- Drift time = 132 ns

- Total time = 185 ns (MAX)

Deconvoluted signal width vs angle

For RUN 5275 the cluster size of X-view is much higher, thus also its number of entries w.r.t. Y-view

Deconvoluted signals width vs charge

- TOP: charge from APV peak
- BOTTOM: charge from deconvoluted signal

- In both cases the low signal width peak is mainly due to the low charge signals (tails of cluster which don't see the full 5mm drift gap?)
- Small dependence of signal width on signal charge (except when saturated)

Front-End response (all)

RUN 5272, 0-1000 ns

The larger shaping time of TIGER E-branch provides less sensitivity to different input signal widths (TIGER E-branch saturation not considered)

Front-End response (1)

RUN 5272, 0-60 ns

With short input signals APV charge is higher than the one from deconvolution

Front-End response (2)

RUN 5272, 60-120 ns

While for longer input signals APV charge is lower than the one from deconvolution (ballistic deficit)

Front-End response (3)

RUN 5272, 120-180 ns

Front-End response (4)

RUN 5272, 180-1000 ns

With very long input signals both electronics show some ballistic deficit, according to their shaping time

integ_time scan (all)

RUN 5272, 0-1000 ns, integ_time=10

integ_time scan

TOP: first 1000 events

BOTTOM: all events, best fit

$$\text{Peak error} = \frac{V_{\text{peak}} - V_{\text{sampled}}}{V_{\text{peak}}} \cdot 100$$

- V_{peak} = E_branch peak voltage
- V_{sampled} = S&H output

➤ This takes into account only the peak error (which can be “optimized”), not the ballistic deficit (which is fixed)

Conclusions

- The input signals duration plays an important role in the charge measurement (ballistic deficit + *integ_time*)
- Signals can be up to 180-200 ns and this implies that the shaped output signal peaking time is largely dependent on the input signals width
- Setting *integ_time* = 7-8 should be slightly better for these kind of signals (test beam, 0° angle), but the optimum is not the same for all the signals
 - Cluster tails seem to behave differently
 - Angled tracks have shorter duration signals and thus would require a lower *integ_time*
- This analysis provides a tool to study the characteristics of GEM signals (from real data) and the response of TIGER
 - Repeat the analysis on runs taken with different configurations (cosmic, gas mixture, 3 mm gap, CGEM geometry, magnetic field ON) and compare with GEM simulations

TIGER (2)

- Divide time by 2: 70 ns
- Peak voltage = 517 mV
- $Q = 43$ fC (almost no ballistic deficit)

- MAX at $integ_time = 6$
- Sampled voltage = 516 mV
- $Q = 43$ fC (peak sampled correctly)

TIGER (3)

- Divide time by 3: 47 ns
- Peak voltage = 521 mV
- $Q = 43.5$ fC (no ballistic deficit)

- MAX at $integ_time = 6$
- Sampled voltage = 519 mV
- $Q = 43.25$ fC

TIGER (4)

- Divide time by 4: 35 ns
- Peak voltage = 522 mV
- $Q = 43.5$ fC (no ballistic deficit)

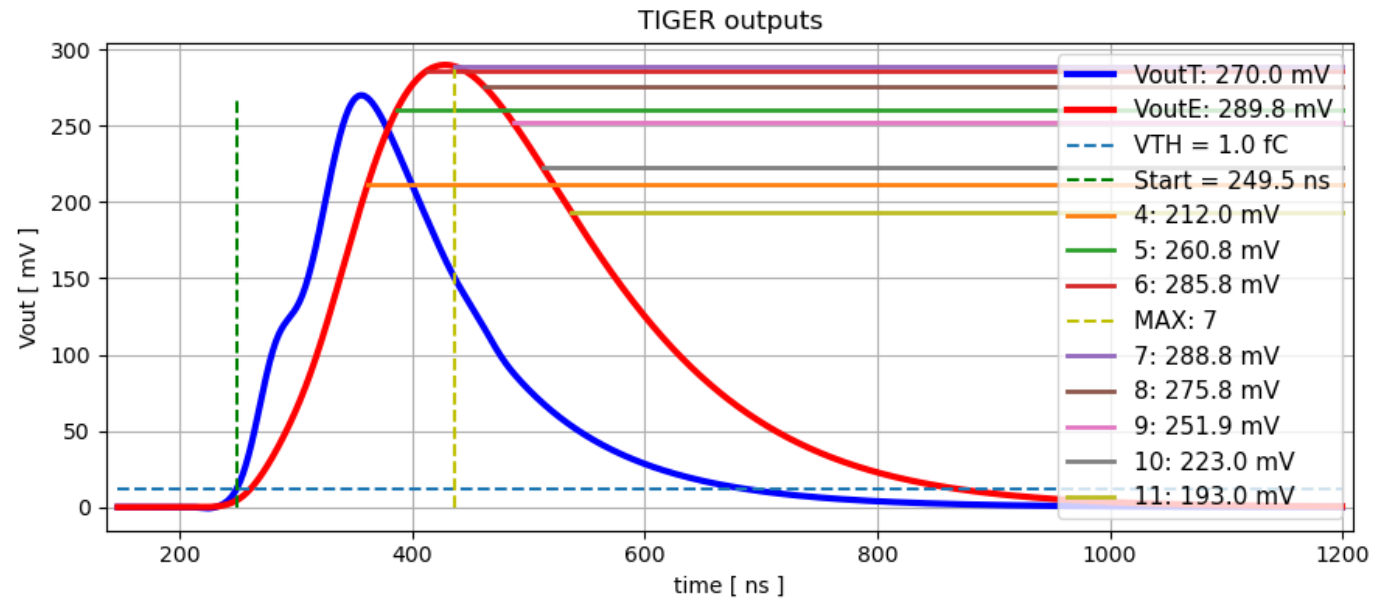

- MAX at $integ_time = 5$
- Sampled voltage = 520 mV
- $Q = 43.3$ fC

TIGER (2)

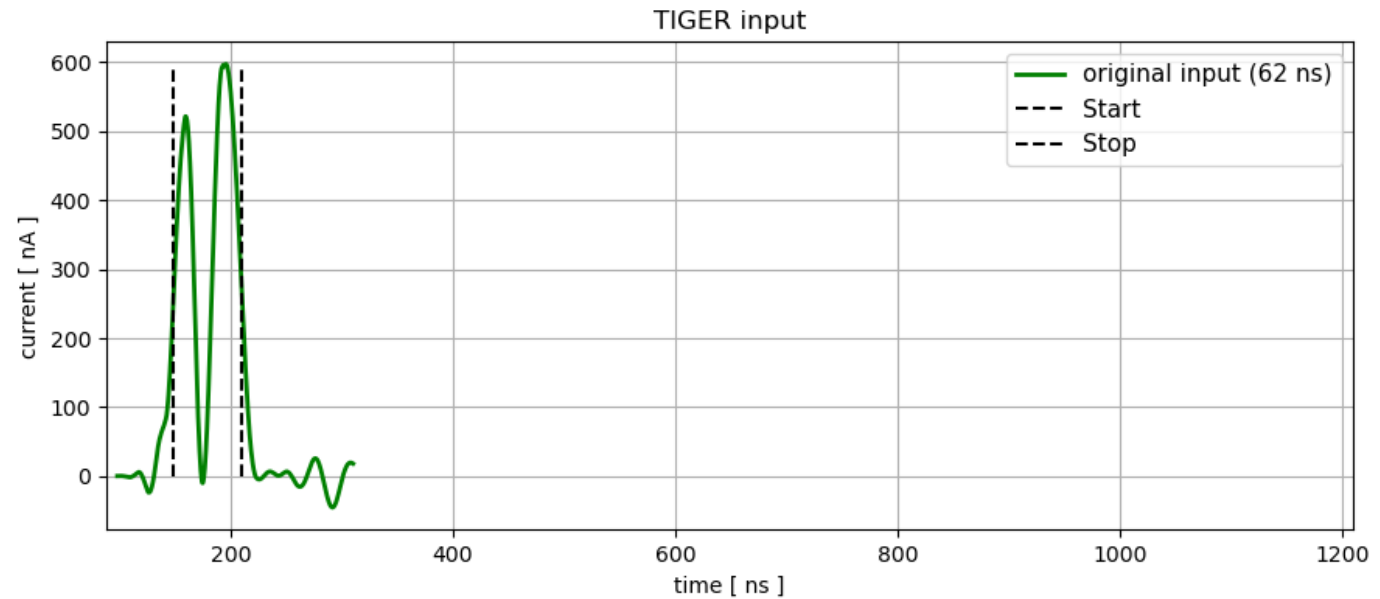

- Divide time by 2: 93 ns
- Peak voltage = 290 mV
- $Q = 24$ fC (almost no ballistic deficit)

- MAX at *integ_time* = 7

TIGER (3)

- Divide time by 3: 62 ns
 - Peak voltage = 297 mV
 - $Q = 25 \text{ fC}$ (no ballistic deficit)
-
- MAX at $integ_time = 6$

TIGER (4)

- Divide time by 4: 46 ns
 - Peak voltage = 299 mV
 - $Q = 25 \text{ fC}$ (no ballistic deficit)
-
- MAX at $integ_time = 5$
