Scattering of J=0,2 glueballs and their thermodynamic properties

Wednesday, 7 June 2023 17:30 (20 minutes)

According to lattice QCD results, the two lightest glueballs are the scalar $(J^{PC} = 0^{++})$ and the tensor $(J^{PC} = 2^{++})$. From the well known dilaton potential that depends on a single dimentionful parameter, Λ_G , we study the scattering of two scalar and two tensor glueballs. From the scattering of two scalar glueballs we find that, using a proper unitarization scheme, a bound state, called glueballonium, can form if Λ_G is small enough. The value of the phase shift obtained from this analysis can than be used in a Glueball Resonance Gas model, that describes the YM thermodynamics in the confined phase, to estimate the correction of the interactions to the pressure.
