Type: **Invited oral presentation**

## **Beam-driven, Plasma-based Particle Acceleration**

*Tuesday, 29 November 2011 14:30 (30 minutes)*

Particle accelerators at the energy frontier are getting ever larger. Plasma-based particle accelerators operate at gradients in the 1-100GeV/m and could become a new, more compact and therefore cheaper accelerator technology. In the plasma wakefield accelerator (PWFA) the accelerating gradient is driven by a short particle bunch. PWFA experiments have already demonstrated energy gain by trailing electrons of 42GeV in only 85cm of plasma. Future experiments are geared toward multi-GeV acceleration of a high quality witness bunch (SLA\_FACET), the extraction of large amounts of energy from a proton drive bunch (MPP-CERN), and large relative energy gain and basic PWFA physics with MeV bunches (BNL-ATF). An introduction to the PWFA, a summary of experimental results, as well as an outlook to future experiments will be given.

**Presenter:** MUGGLI, Patric (Max-Planck-Institut für Physik (MPP), Munich, Germany)

**Session Classification:** Satellite Meeting
