

Implications of first LHC results

- 1) Large extra dimensions (<http://arxiv.org/abs/1101.4919>)
- 2) SuperSymmetry (<http://arxiv.org/abs/1101.2195>)

Alessandro Strumia

with R. Franceschini, G. Giudice, P. Paolo Giardino, P. Lodone

The main goal of LHC

is understanding why the weak scale is small.

Maybe the hierarchy problem was a good guideline. Maybe we lost 30 years.

A new symmetry

Scalar

$$H \rightarrow H + \theta$$

Keeps H massless.
Goldstone boson.

Vector

$$A_\mu \rightarrow A_\mu + \partial_\mu \theta$$

Keeps A_μ massless
In 5 dims: $H = A_5$

Fermion

$$\Psi \rightarrow e^{i\theta\gamma_5}\Psi$$

Keeps Ψ massless.
 $H \overset{\text{SUSY}}{\leftrightarrow} \Psi$.

Higgs has weak-scale size

Technicolour

H bound state like π

Large extra dims

H is a string or...

Warped extra dims

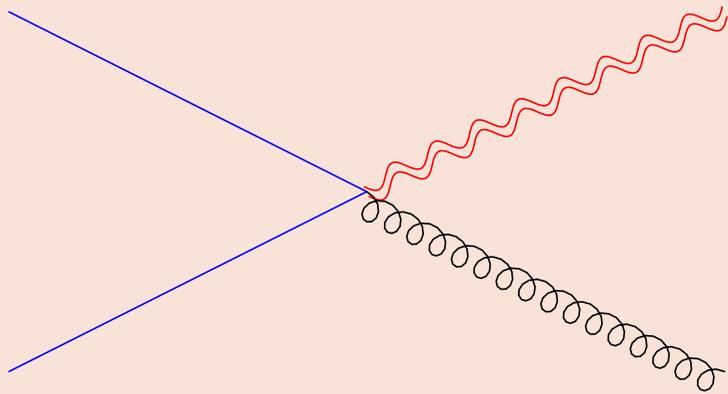

Dual to technicolor

Large extra dimensions

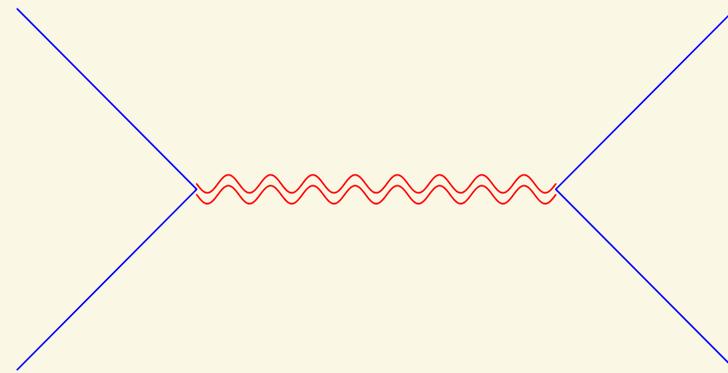

Collider signals

Quantum gravity is unknown; signals computable at $E \ll M_D$ and $E \gg M_D$:

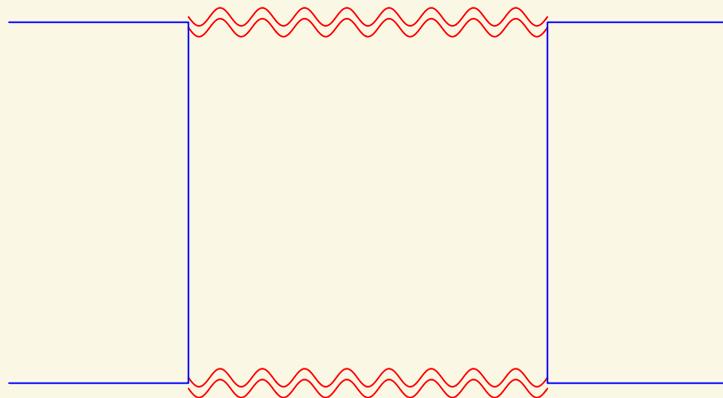

(1) Graviton emission

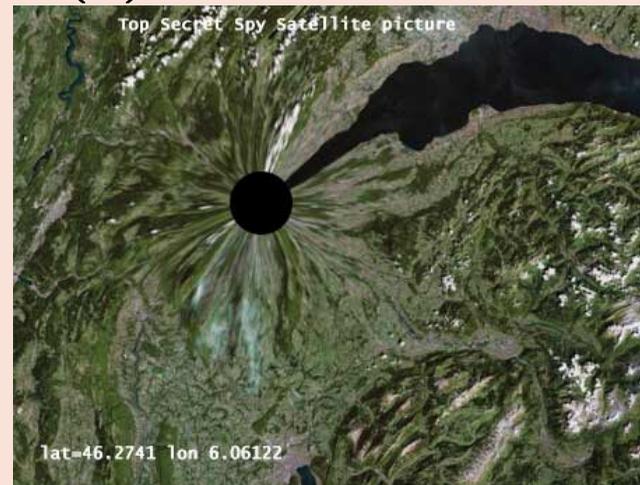

(2) Tree-level graviton exchange

(3) Graviton loop

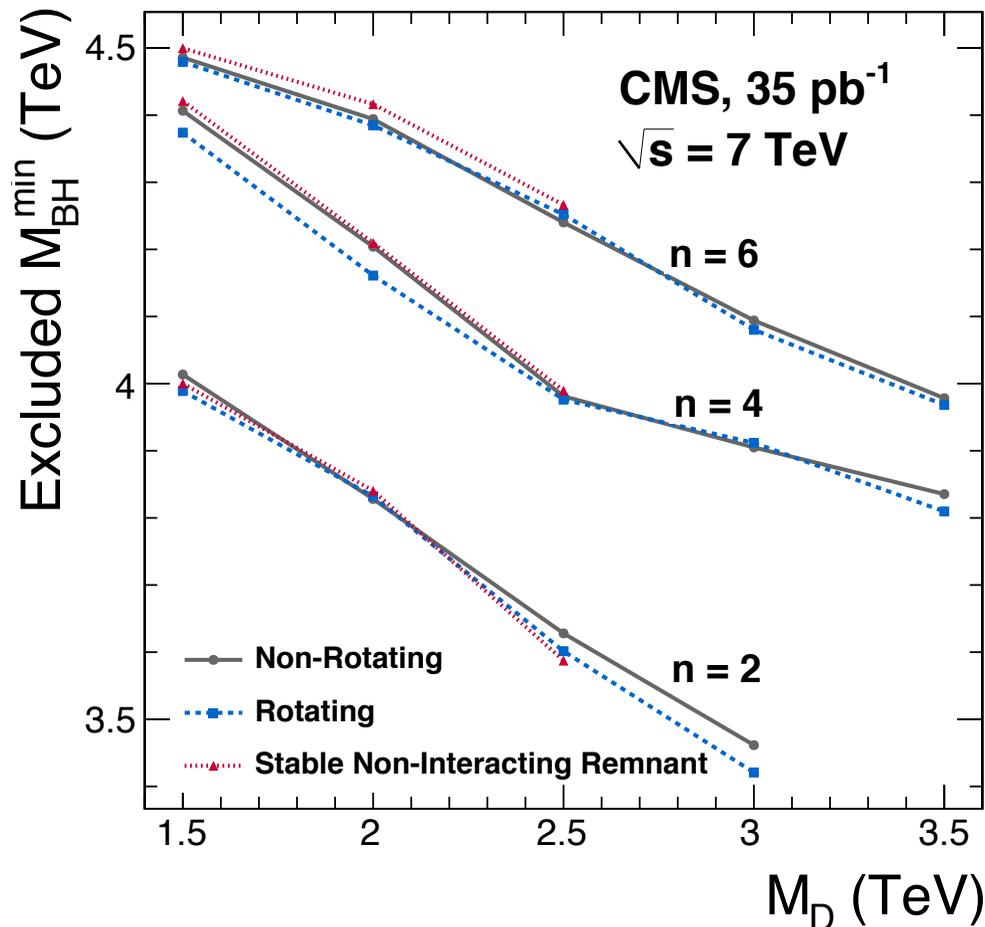

(4) Trans-Planckian

No black holes in first LHC data

$$\sigma \sim (M_{\text{BH}}/M_D)^{2/(\delta+1)}/M_D^2 \text{ depends on } M_{\text{BH}} > M_{\text{BH}}^{\text{min}} \gtrsim M_D$$

First LHC data: $pp \rightarrow jj$

ATLAS at 3.1/pb

CMS at 36/pb

χ = angular jj distance. Coulomb-like QCD gives a quasi-flat distribution. New massive particles or effective \mathcal{O} give effects at large M_{jj} and small angle χ

Loop level graviton exchange

At low energy is described by the dimension 6 effective operator

$$\mathcal{L} = c_\gamma \times \Upsilon, \quad \Upsilon = \frac{1}{2} \left(\sum_f \bar{f} \gamma_\mu \gamma_5 f \right)^2$$

95% CL limits on $ c_\gamma/4\pi ^{-1/2}$ in TeV			
Experiment	Process	+	-
LEP combined	$e^+e^- \rightarrow l^+l^-$	17.2	15.1
LEP combined	$e^+e^- \rightarrow b\bar{b}$	15.3	11.5
ZEUS, H1	e^+p and e^-p	4.6	5.3
DØ	$p\bar{p} \rightarrow e^+e^-$	4.7	5.5
CDF	$p\bar{p} \rightarrow l^+l^-$	4.5	5.6
CCFR	νN scattering	3.7	5.9
DØ	$p\bar{p} \rightarrow jj$	3.2	3.1
ATLAS at 7 TeV with 3.1/pb	$pp \rightarrow jj$	5.3	4.2
CMS at 7 TeV with 36/pb	$pp \rightarrow jj$	11	8.1
combined		22.4	15.7

LHC improves on TeVatron but not on LEP

Tree level graviton exchange

At low energy is described by the dimension 8 effective operator $\mathcal{L}_{\text{eff}} = c_{\mathcal{T}} \mathcal{T}$

$$\mathcal{T} = \frac{1}{2} \left(T_{\mu\nu} T^{\mu\nu} - \overbrace{\frac{T_{\mu}^{\mu} T_{\nu}^{\nu}}{\delta + 2}}^{\text{irrelevant}} \right)^2 \sim (\bar{\Psi} \partial \Psi + \bar{\Psi} A \Psi + F_{\mu\nu}^2)^2$$

Independently produced by brane fluctuations at loop level.

High dimensionality: energy is the key factor and early LHC wins

Coefficient: parameterize as $c_{\mathcal{T}} = 8/M_{\mathcal{T}}^4$ (Hewett normalization).

Signals: $pp \rightarrow jj$ is considered dirty by actually is much better at low statistics:

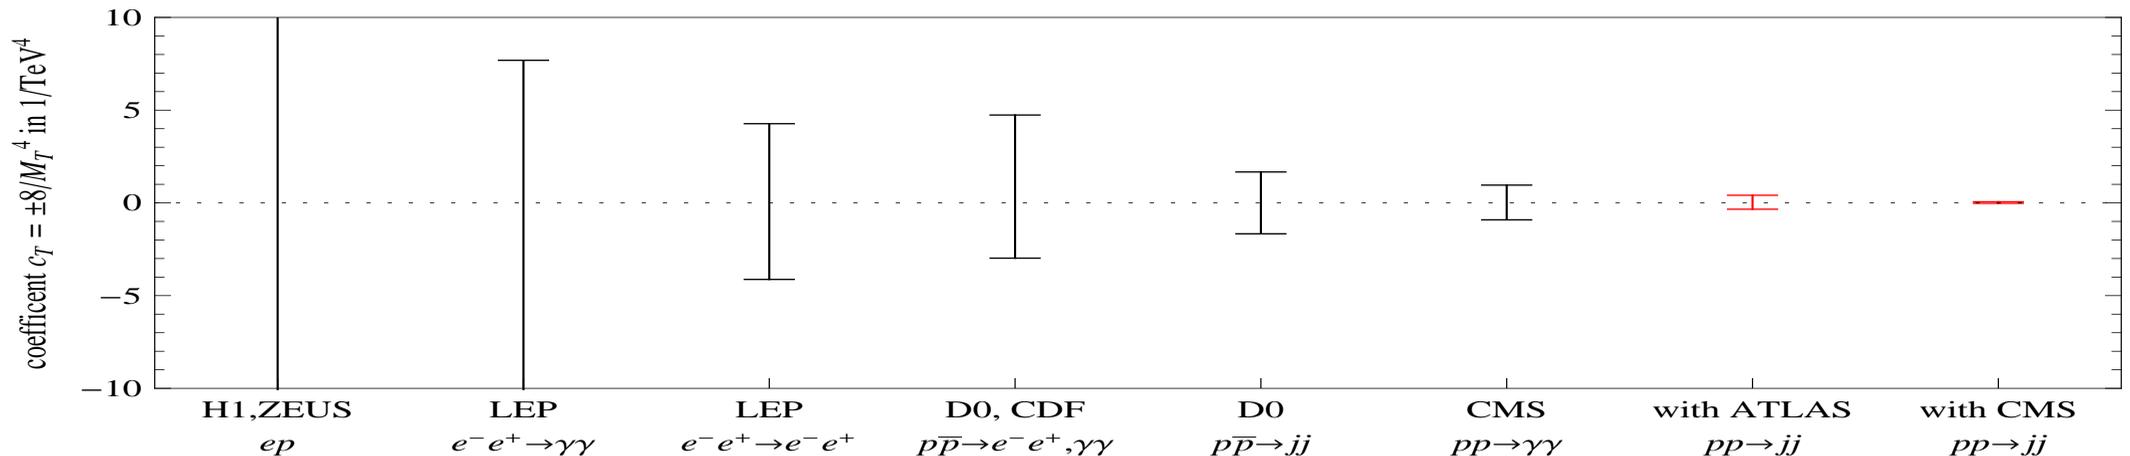

$$\sigma = \left(\frac{2 \text{ TeV}}{M_{\mathcal{T}}} \right)^8 \times \begin{cases} 12.5 \text{ pb} & \text{for } pp \rightarrow jj \\ 10.4 \text{ fb} & \text{for } pp \rightarrow \mu^+ \mu^- \\ 21.3 \text{ fb} & \text{for } pp \rightarrow \gamma\gamma \end{cases}$$

thanks to the energetic $uu \rightarrow uu$. (cuts: $\sqrt{s} = 7 \text{ TeV}$, $M_{\text{eff}} > 1 \text{ TeV}$, $\eta < 2.5$)

Bounds on $M_{\mathcal{T}}$

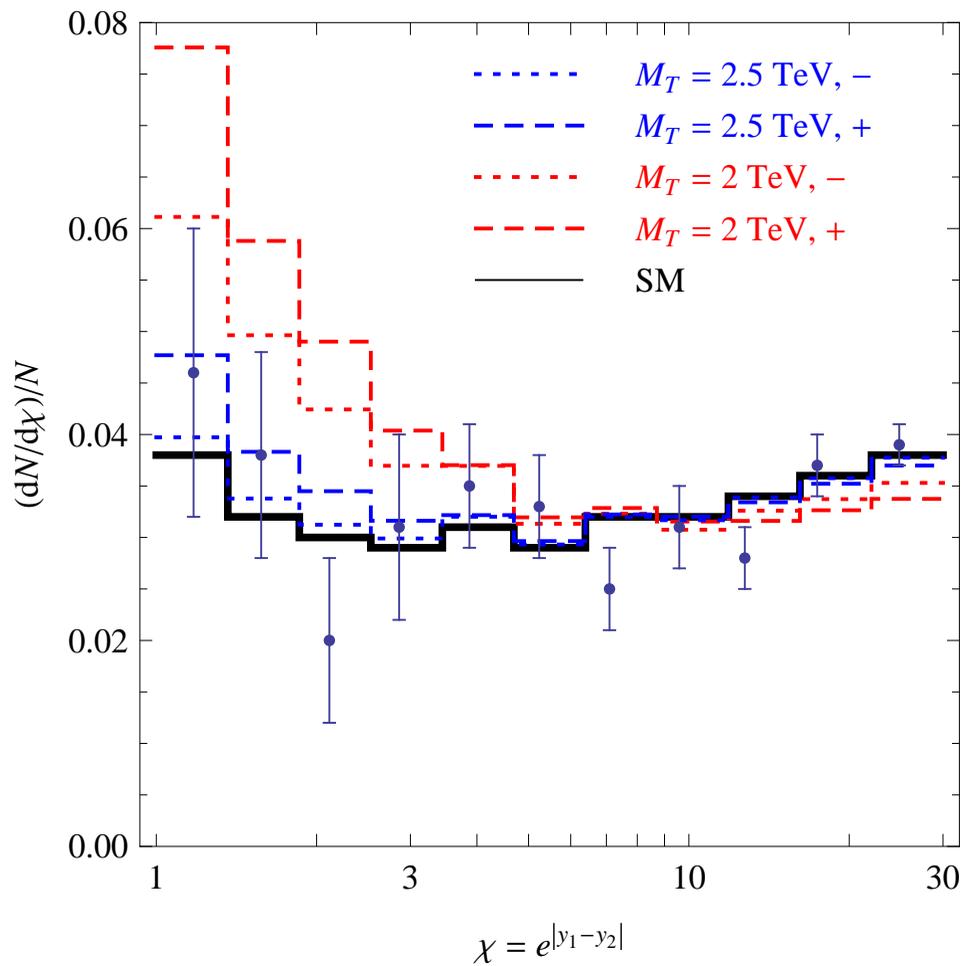

Experiment	Process	+	-
LEP	$e^+e^- \rightarrow \gamma\gamma$	0.93 TeV	1.01 TeV
LEP	$e^+e^- \rightarrow e^+e^-$	1.18 TeV	1.17 TeV
H1, ZEUS	e^+p and e^-p	0.74 TeV	0.73 TeV
CDF	$p\bar{p} \rightarrow e^+e^-, \gamma\gamma$	0.99 TeV	0.96 TeV
DØ	$p\bar{p} \rightarrow e^+e^-, \gamma\gamma$	1.28 TeV	1.14 TeV
DØ	$p\bar{p} \rightarrow jj$	1.48 TeV	1.48 TeV
CMS at 7 TeV with 34/pb	$pp \rightarrow \gamma\gamma$	1.72 TeV	1.70 TeV
ATLAS at 7 TeV with 3.1/pb	$pp \rightarrow jj$	2.2 TeV	2.1 TeV
CMS at 7 TeV with 36/pb	$pp \rightarrow jj$	4.2 TeV	3.4 TeV

Bounds on graviton exchange at tree level

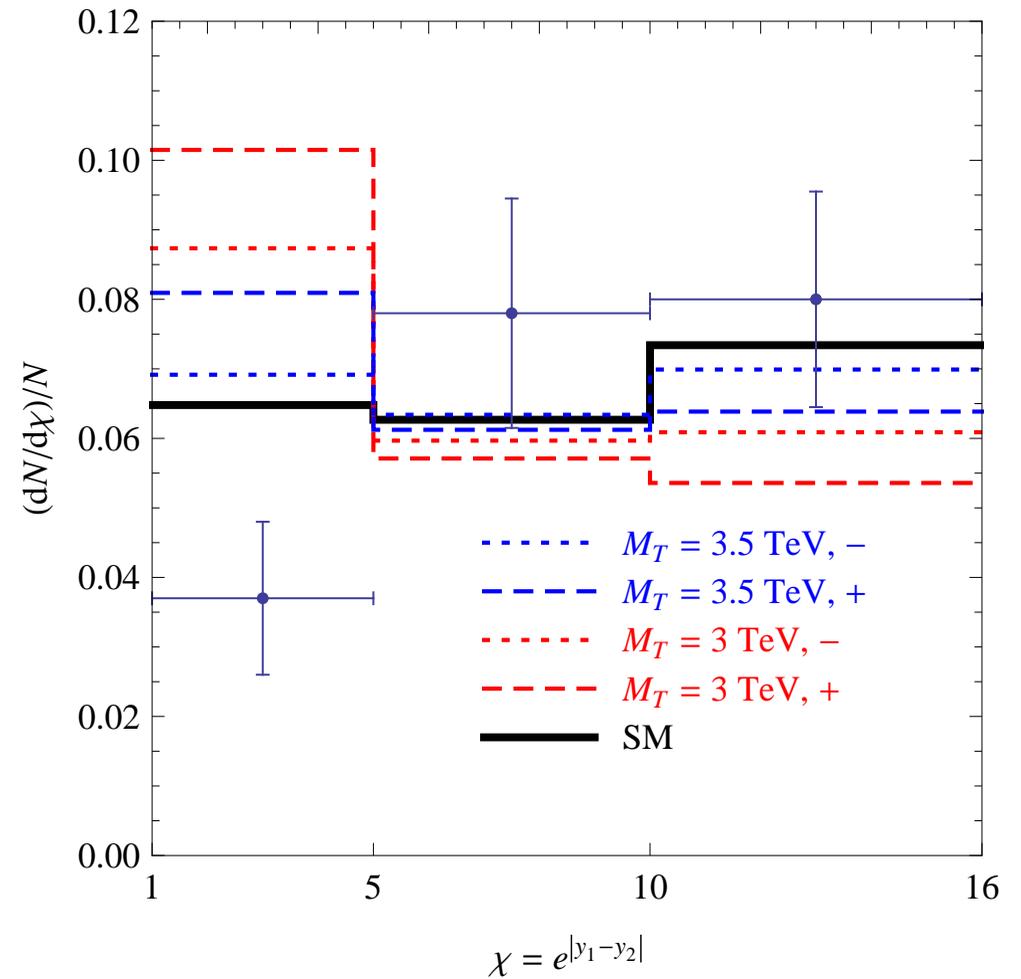

The LHC data

$pp \rightarrow jj$, ATLAS, 3.1 pb^{-1} , $M_{jj} > 1.2 \text{ TeV}$

$pp \rightarrow jj$, CMS, 36 pb^{-1} , $M_{jj} > 2.2 \text{ TeV}$

Computed implementing in MadGraph and Pythia

Fitting the full amplitude $\mathcal{A} = \mathcal{S}(s)T_{\mu\nu}^2$

Truncate KK tower at $m < \Lambda$ to avoid UV divergence:

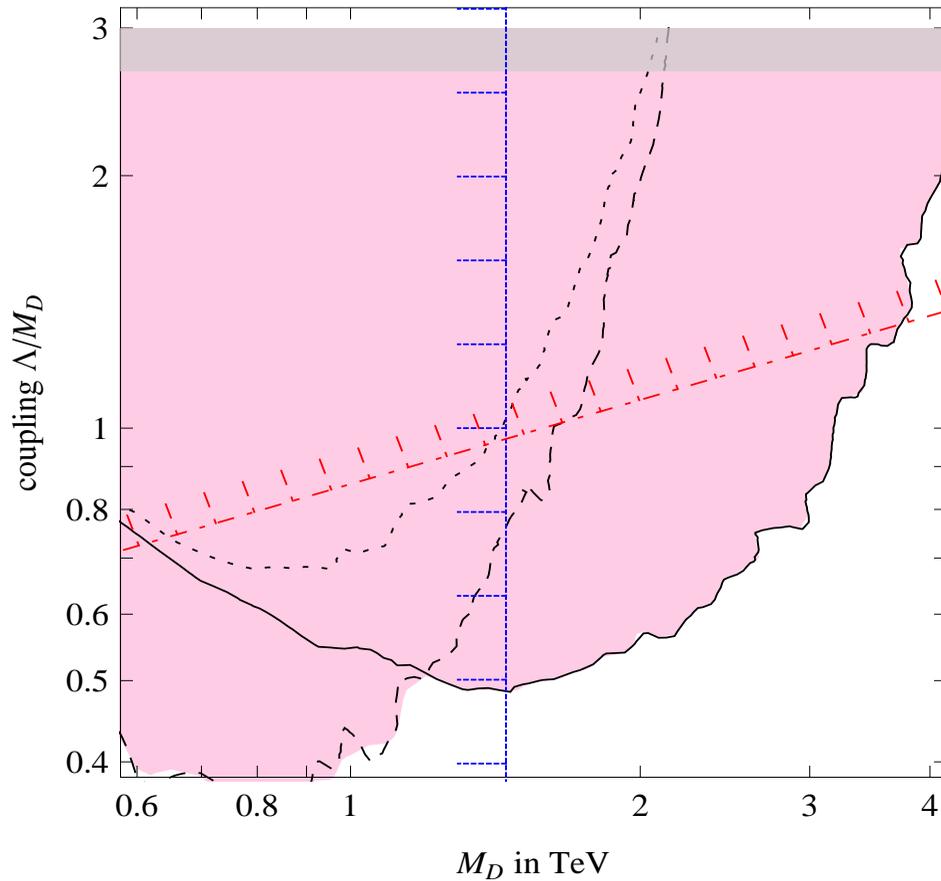

$$\mathcal{S}(s) = \frac{1}{M_{\text{Pl}}^2} \sum_i \frac{1}{s - m_i^2 + im_i \Gamma_G(m_i)} = \frac{1}{M_D^{2+\delta}} \int_{|q| < \Lambda} \frac{d^\delta q}{s - q^2 + i\epsilon}$$

$$c_{\mathcal{T}} = \mathcal{S}(s \ll \Lambda^2) = \begin{cases} \frac{\pi^{\delta/2}}{(1 - \delta/2)\Gamma(\delta/2)} \frac{\Lambda^{\delta-2}}{M_D^{\delta+2}} \equiv \frac{8}{M_{\mathcal{T}}^4} & \text{for } \delta > 2 \\ \frac{\pi}{M_D^4} \ln \frac{s}{\Lambda^2} & \text{for } \delta = 2 \\ \frac{-i\pi}{M_D^3 \sqrt{s}} & \text{for } \delta = 1 \end{cases}$$

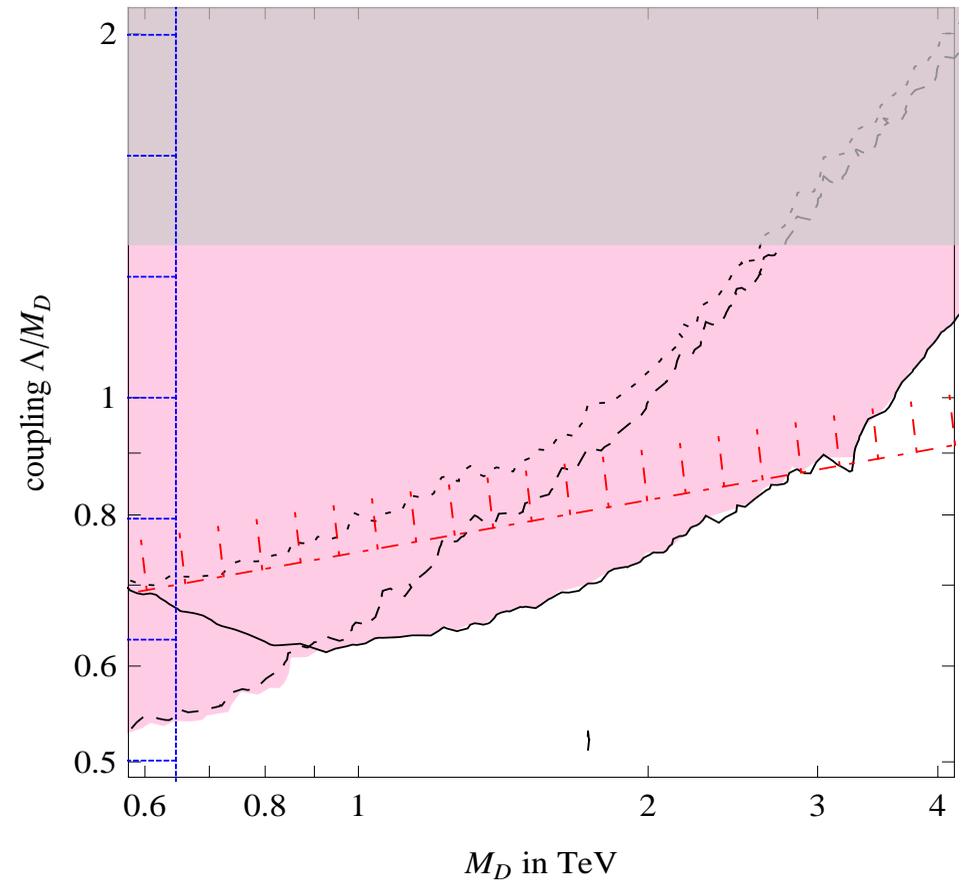

Subtlety: $\mathcal{S}_f = \langle \mathcal{S}_\Sigma \rangle$ i.e. it is ok to $\sum_{\text{KK}} \approx \int_q$ and ignore the graviton width

Bound on the full amplitude (M_D, Λ)

$\delta = 2$ extra dimensions

$\delta = 6$ extra dimensions

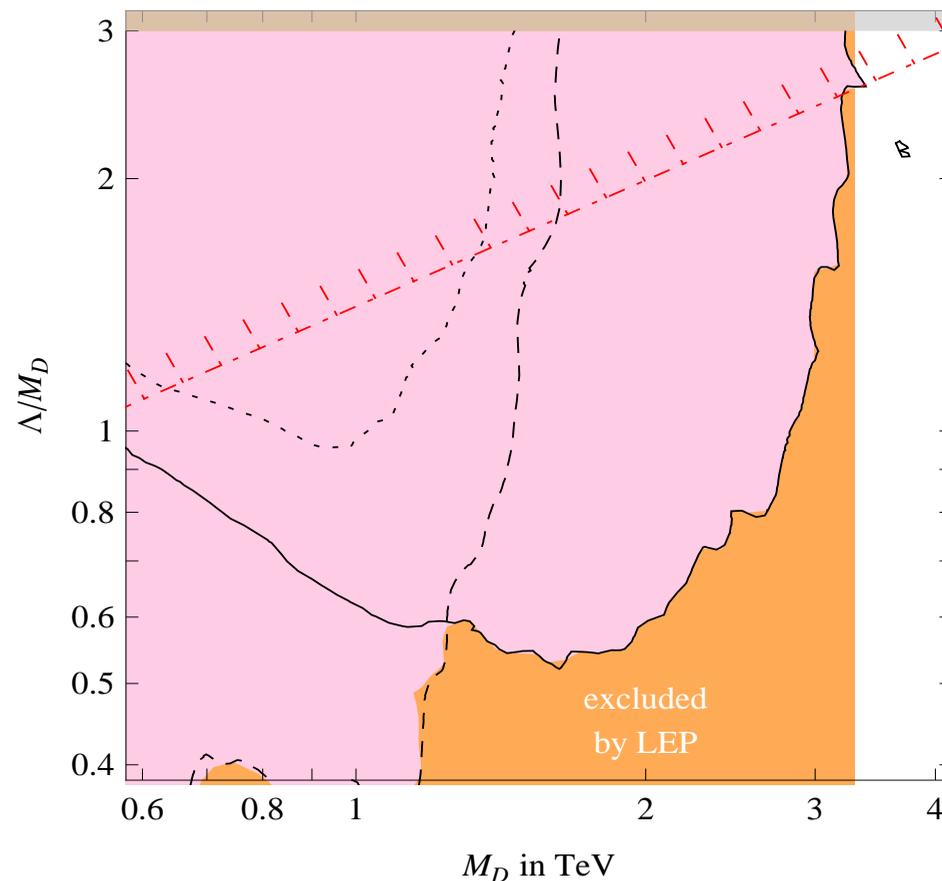

- Shaded: LHC (continuous = CMS; dashed = ALTAS; dotted ATLAS F_{χ})
- Blue: graviton emission, ignoring the dependence on Λ
- Red: NDA estimate of graviton loop
- Gray: non-perturbative quantum gravity

Bound on the full amplitude (M_D, Λ)

A bit of warping makes less KK gravitons with larger couplings: $\delta = 1$ is allowed.
But special: gravitons decay promptly in the detector:

- graviton production gives no \cancel{E}_T signals.
- tree level exchange of *virtual and real* gravitons give $e^+e^- \rightarrow \ell^+\ell^-$ and $pp \rightarrow jj$.

$\delta = 1$ extra dimensions

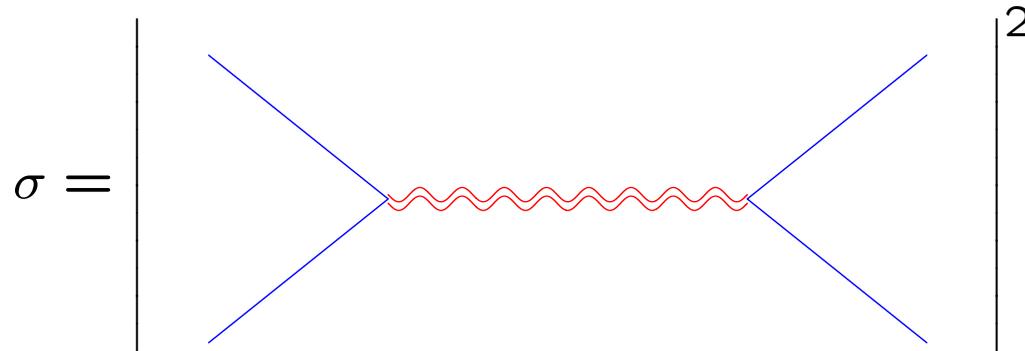

$\delta > 1$: how to subtract real gravitons?

$\Gamma_G = 283m^3/960\pi M_{\text{Pl}}^2$ is small: gravitons decay far away. But the S -matrix keeps them: $\langle |S|^2 \rangle = (\text{Re } S)^2 + (\text{Im } S)^2/\epsilon$ with $\epsilon = \pi\Gamma_G/2\Delta m \sim (s/M_D^2)^{1+\delta/2}$.

Resonant graviton production must be subtracted

Consider just one particle with coupling g ($g \sim E/M_{\text{Pl}} \ll 1$ for KK gravitons):

One would guess $\sigma \sim g^4$ but actually $\sigma \sim g^2$, due to $pp \rightarrow$ graviton. Next graviton decays with 100% probability and width $\Gamma \sim mg^2$.

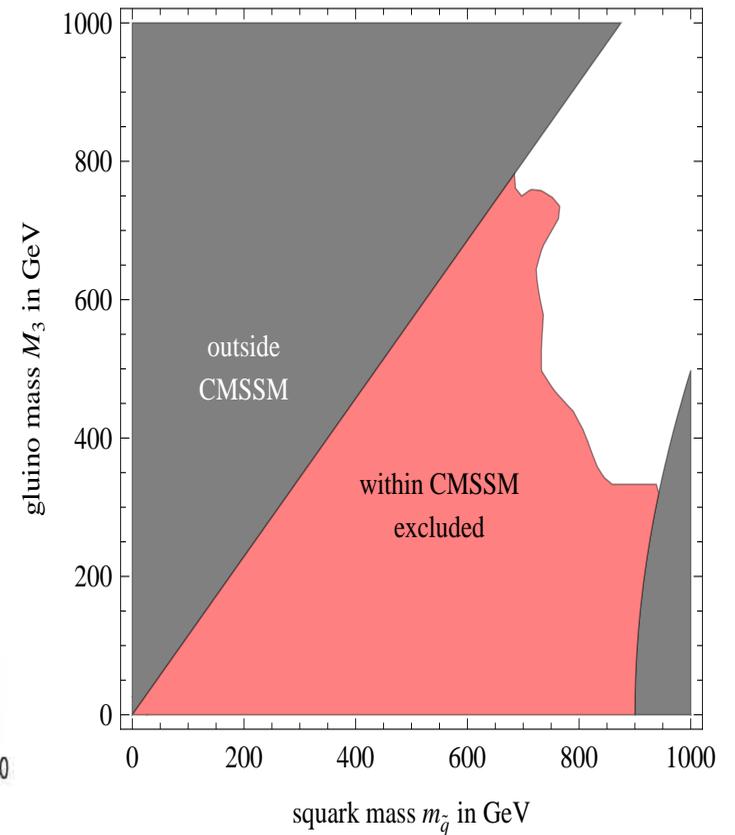

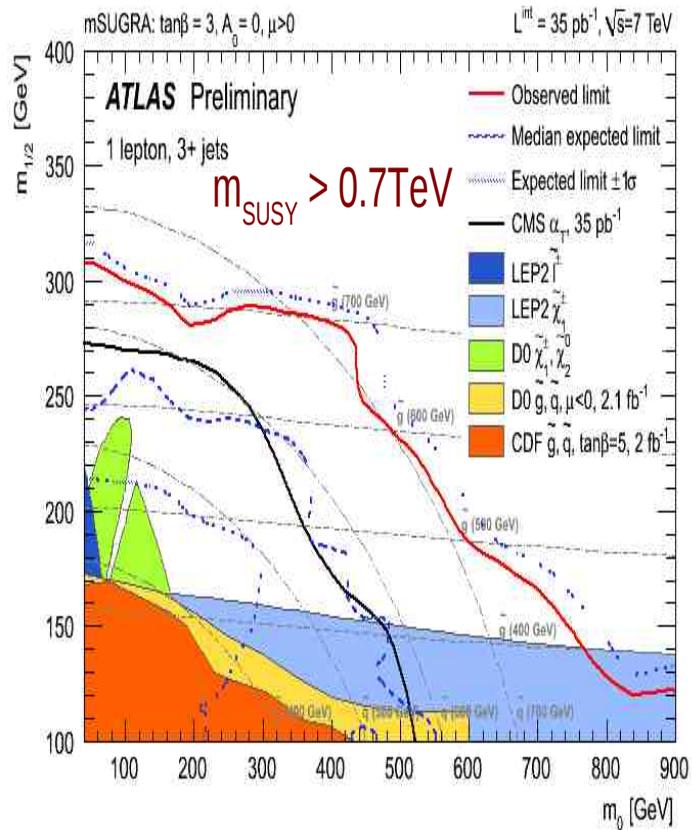

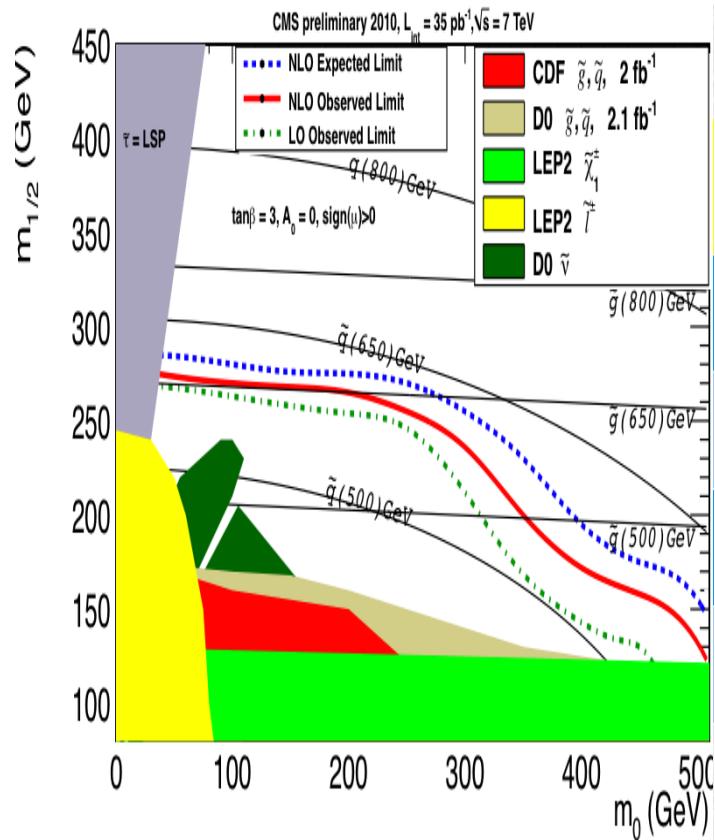

We find $\sigma_{\text{subtracted}} \sim -g^4$, up to $\mathcal{O}(g^4)$ terms, such as NLO corrections to Γ .

We presume that $\langle |S|^2 \rangle_{\text{subtracted}} = |\langle S \rangle|^2$ is the right result

Anyhow, even the unsubtracted $1/g^2$ enhancement (present for $\delta = 1$) is numerically irrelevant for $pp \rightarrow jj$.

SUSY

First LHC data

Actually a bound on $m_{\tilde{q}}$ and M_3 , up to 700 GeV in the CMSSM

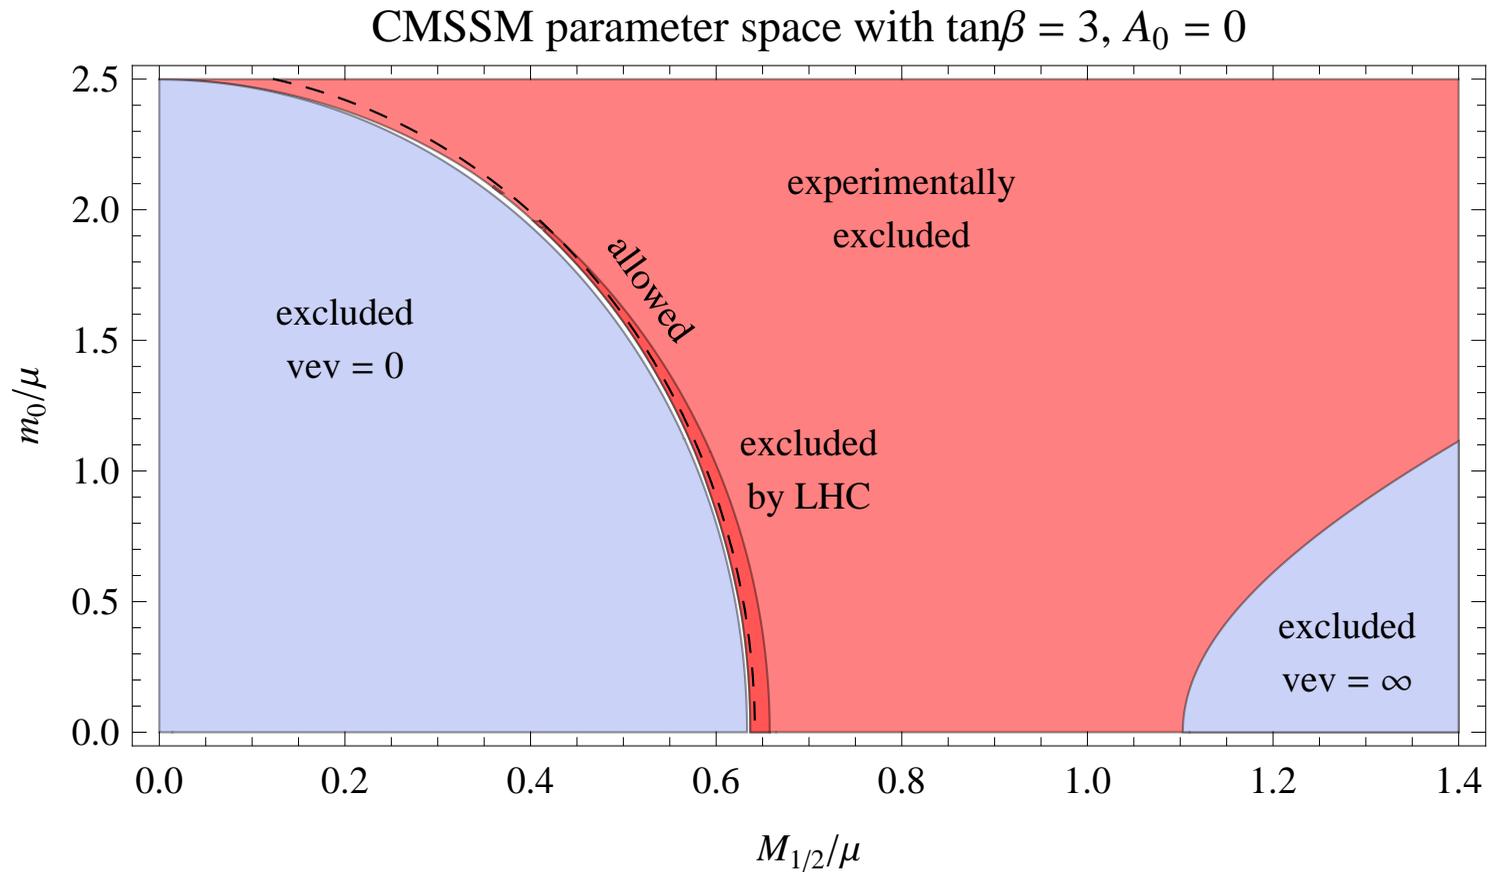

In the following we ignore $g_\mu = 2$ or Ω_{DM} ; they point to heavier m_{SUSY} .

The little hierarchy problem

Fix $\tan\beta = 3$ and $A_0 = 0$; the overall SUSY mass scale is fixed by

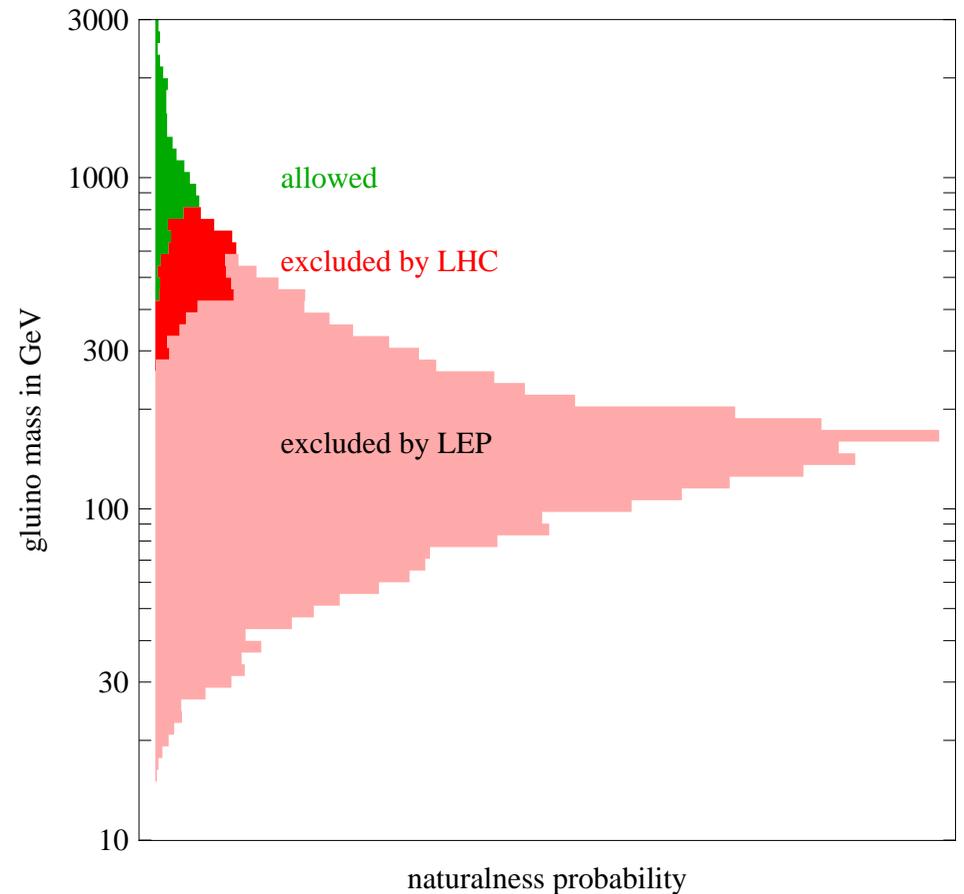

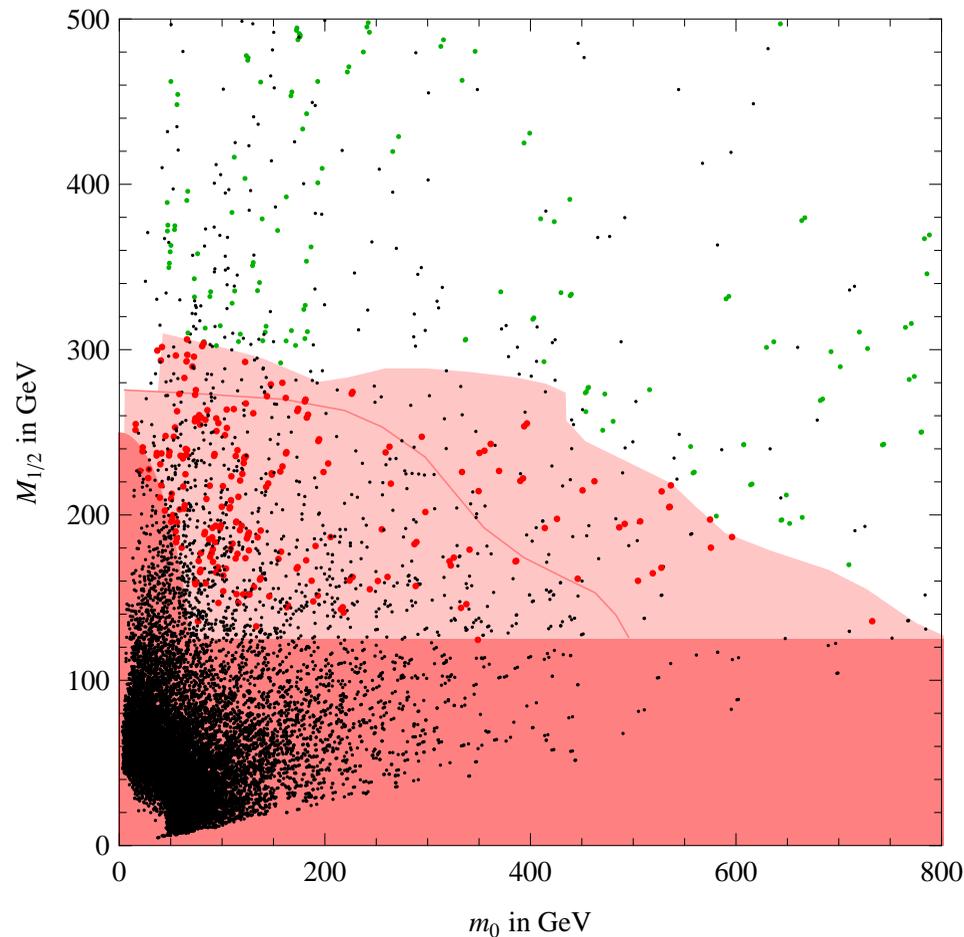

$$m_h^2 \xrightarrow{\text{tree level}} M_Z^2 \approx 0.2m_0^2 + 0.7M_{1/2}^2 - 2\mu^2 = (91 \text{ GeV})^2 \times 35 \left(\frac{M_3}{650 \text{ GeV}}\right)^2 + \dots$$

Plot this in the plane of the adimensional free parameters $(M_{1/2}, m_0)/\mu$:

Bayesian MonteCarlo technique

Scan over all adimensional parameters (m_0/μ , $B_0/m_0, \dots, \lambda_t$) compatible with measured m_t . Compute $\tan \beta$ and m_{SUSY} from V_{MSSM} . Normally $m_{\text{SUSY}} \sim M_Z$; rare accidents can make it bigger. All possible fine-tunings are included without using any explicit FT parameter Δ . E.g. focus point is fine-tuning of λ_t .

Black dot = excluded spectrum. Red = excluded by LHC. Green = allowed

Fraction of alive CMSSM $\approx 1/\Delta$

Fraction of surviving CMSSM parameter space

any m_h

$m_h > 100$ GeV

$m_h > 110$ GeV

10.% after LEP

4.% after LEP

1.% after LEP

3.% after LHC

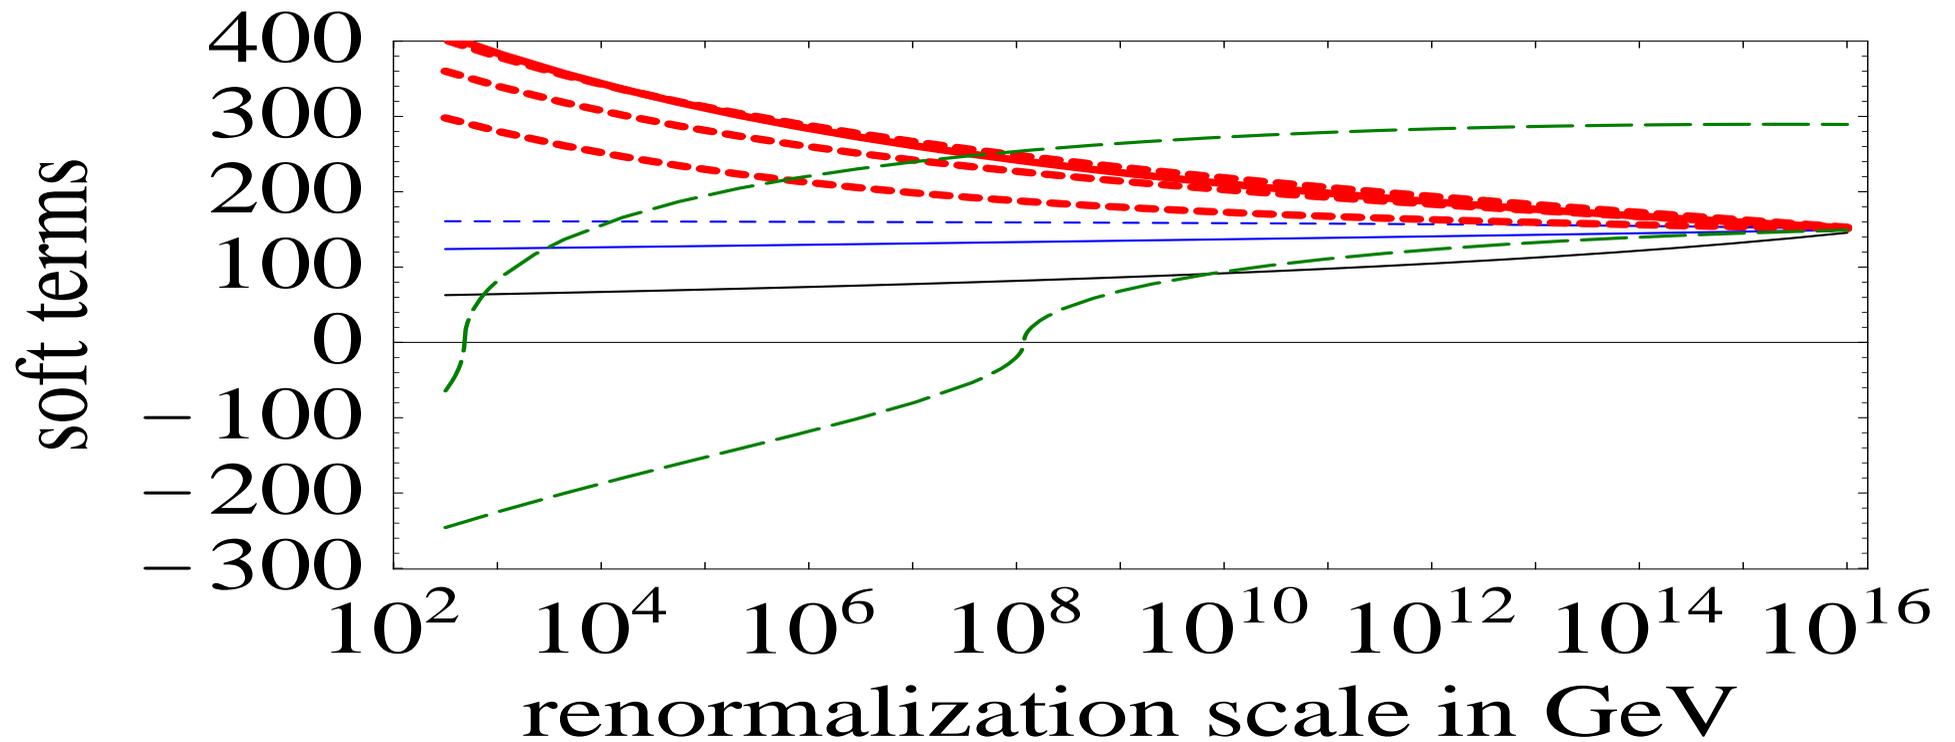

1.5% after LHC

0.7% after LHC

(The CMSSM prediction for m_h can be circumvented;
the theoretical uncertainty in m_h is about 3 GeV)

$M_Z \ll m_{\text{SUSY}} \Rightarrow$ late **SU(2)** breaking

The scale Q_0 at which RGE running makes $m_h^2(Q) < 0$ must be close to m_{SUSY}

SUSY little Higgs as pseudo-Goldstone of some symmetry broken at Q_0 ?

The sliding m_{SUSY} model

Assume that m_{SUSY} is a free parameter determined by minimizing V_{MSSM} (!)

$$\min V_{\text{MSSM}} \sim \begin{cases} 0 & m_{\text{SUSY}} > Q_0 \\ -m_{\text{SUSY}}^4 & m_{\text{SUSY}} < Q_0 \end{cases}$$

Prediction [hep-ph/0005203, BS]: $m_{\text{SUSY}} \lesssim Q_0$ and a loop factor above M_Z :

$$\frac{d\mu_u^2}{d\ln\mu} \sin^2\beta + \frac{d\mu_d^2}{d\ln\mu} \cos^2\beta - 2\frac{d\mu_{ud}^2}{d\ln\mu} \sin\beta \cos\beta = M_Z^2 \cos^2 2\beta \xrightarrow{\text{one loop}} m_h^2$$

RGE loop factors are big: roughly this means

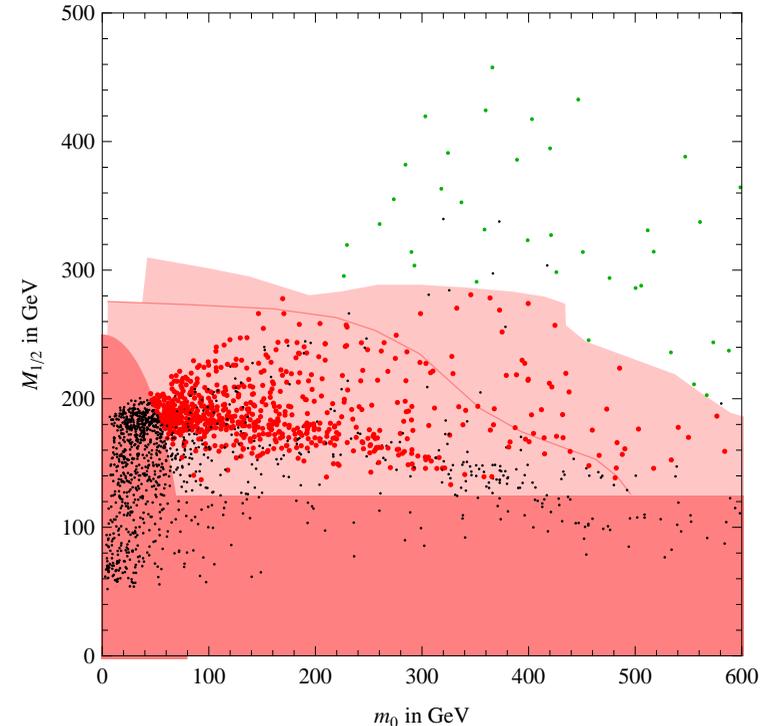

$$m_{\tilde{f}} \approx 4\pi M_Z / \sqrt{12} \approx 400 \text{ GeV}$$

Predicted: dashed line in the CMSSM plot.

Allowed: from 50% to 6% with LHC.

PS: BS hypothesis may be BS: $V \neq V_{\text{MSSM}}$.

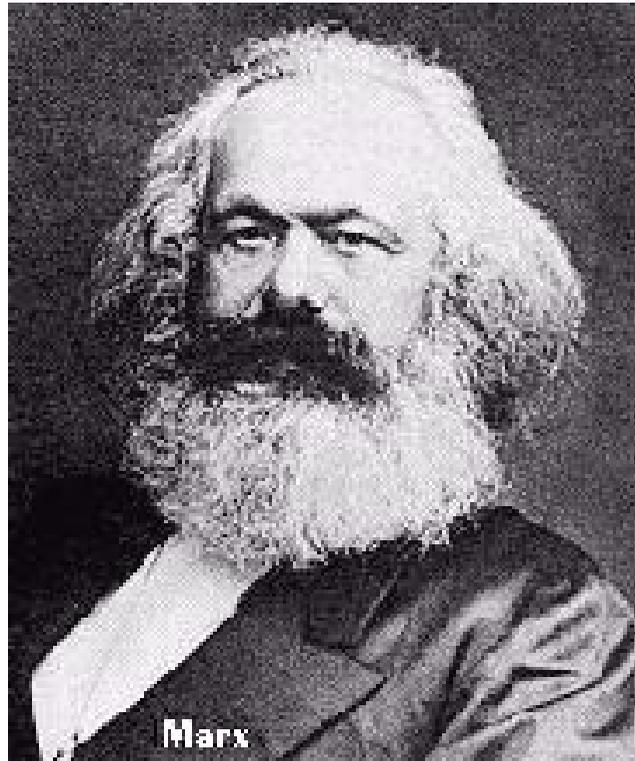

Alternative interpretation in terms of anthropic pressure ($Q_0 \ll m_{\text{SUSY}}$): more rare than SM?

Conclusions

These beautiful ideas and the history of the Michelson-Morley experiment teach us that a negative experimental search can have deep theoretical implications.

“History repeats itself, first as tragedy, second as farce” .

Marx

Conclusions

*“Now this is not the end.
It is not even the beginning of the end.
But it is, perhaps, the end of the beginning”.*
