- CNN developed and trained in **Matlab**
- Accuracy and ROC_AUC reached about 90%.

- Original DBT slices were pre-processed, resized to 300 x 300 px and fed independently to the CNN.
- CNN trained on the full dataset (CC), but with slices of validation patient present also in the training set.

Fig. 4. Deep Convolutional Neural Network architecture developed for this work. It is made up of 24 convolution levels: 1 level input, 5 convolutional levels, 2 fully connected classification levels and finally 1 softmax level immediately followed by an output level.

DL for BDT classification: The aims of the new work

- Adoption of **python** for the whole pipeline of processing, training and analysis
- **Optimization** of the considered CNN and investigation of other models
- Test the model on **other/mixed datasets**
- Managing of **different projections** (apart from CC)
- **Extension to 3 classes classification** (negative, malign, benign)

DL for BDT classification: python implementation

We developed a **tool composed of a set files (one main script)**, to:

- **Compose properly** the datasets (it is the main limitation of the previous work)
- Define the model architecture (we used **TensorFlow** Keras) from scratch or import known ones
- Perform hyperparameter optimization and/or a k-fold cross-validation
- Train the model on the full dataset and calculate automatically a variety of metrics and produce useful plots
- Calculate, plot and export the activation (saliency) maps

All the variables that define the behaviour of each script are grouped at the beginning («input section») to make its use simple even for non expert users.

DL for BDT classification: python implementation

Features implemented and issues solved:

- Full (and automatic) support of classification in 3 classes
- Creation of datasets with an (automatic) selection of slices for each patient/projection
- Merging of different datasets pre-processed in the same way
- Data augmentation (flip, zoom, rotate, shift) with random sampling
- Implementation of a Data Generator (to avoid memory issues)
- Automatic split of data in train/validation or import reserved validation data
- Selection among different CNN architectures (some of them are customizable)
- Adoption of regularizers (L2) and dropout
- Transfer learning
- Hyperparameter optimization with Grid or Random Search and k-fold cross-validation
- Automatic setting of the best parameters obtained during hyperparameter optimization and/or the training on the full dataset
- Perform the training of the model on CPU, GPU or multiple GPUs by setting a couple of variables
- Calculation of metrics, confusion matrix, and ROC on train/validation/test sets
- Calculation, plot and export of the activation maps (Grad-CAMs) for all or a sample of images

DL for BDT classification: considered datasets

Dataset	Mammographic unit	Number of patients	Projections	Total slices
Cardarelli	IMS Giotto Class 40000	100 (all with positive biopsies)	CC (L or R)	7496 (3970N + 3526P)
Duke	Hologic	> 1000 (<10% positive), up to now used 102 (32N + 70P)	CC, MLO (L/R)	6191 (3959N + 2232P)
IFO	IMS Giotto Class 40000	40	MLO (L/R)	4062 (2357N + 1705P)

- To **avoid overfitting**, **10 slices per projection** were selected out of the whole set and about **20% patients** were reserved for **validation/test** (the same for various pre-processing level. This was repeat 5 time with random sampling -> manual **5-fold cross validation** (automatic mode was not useful...)).
- Due to decimation, about **25% of the images were used** for training (increased to 42% with data augmentation).

DL for BDT classification: image pre-processing

A dedicated tool has been developed in Matlab by **D. Esposito (INFN-NA)**

DL for BDT classification: results – 3 classes CC slices

DBT_DCNN simplified: less and smaller filters of conv layers and a much smaller final dense layer (from about 2×10^8 param to less than 1×10^6).

5-fold cross-validation

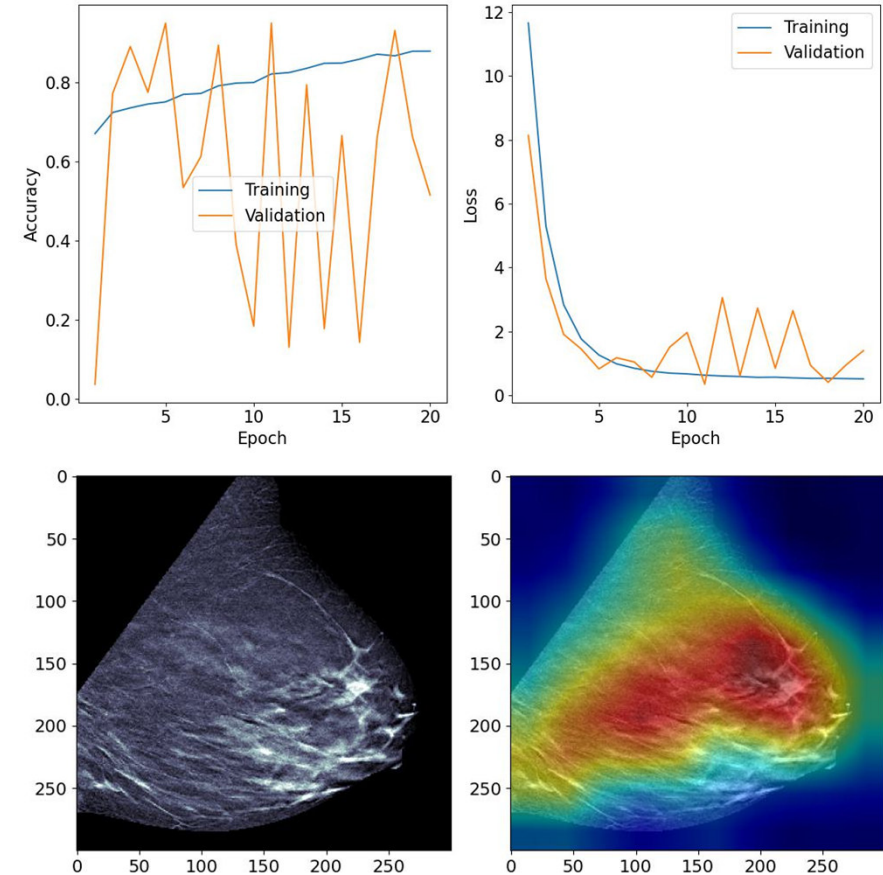

Confusion matrix

Actual	Predicted			sum_col
	Negative	positive	Benign	
	234 40.77%	59 10.28%	5 0.87%	298 78.52% 21.48%
	23 4.01%	102 17.77%	11 1.92%	136 75.00% 25.00%
Benign	27 4.70%	100 17.42%	13 2.26%	140 9.29% 90.71%
	284 82.39% 17.61%	261 39.08% 60.92%	29 44.83% 55.17%	574 60.80% 39.20%
sum_lin				

DL for BDT classification: results – 2 classes CC + MLO slices

DBT_DCNN simplified: less and smaller filters of conv layers and a much smaller final dense layer (from about 2×10^8 param to less than 1×10^6).

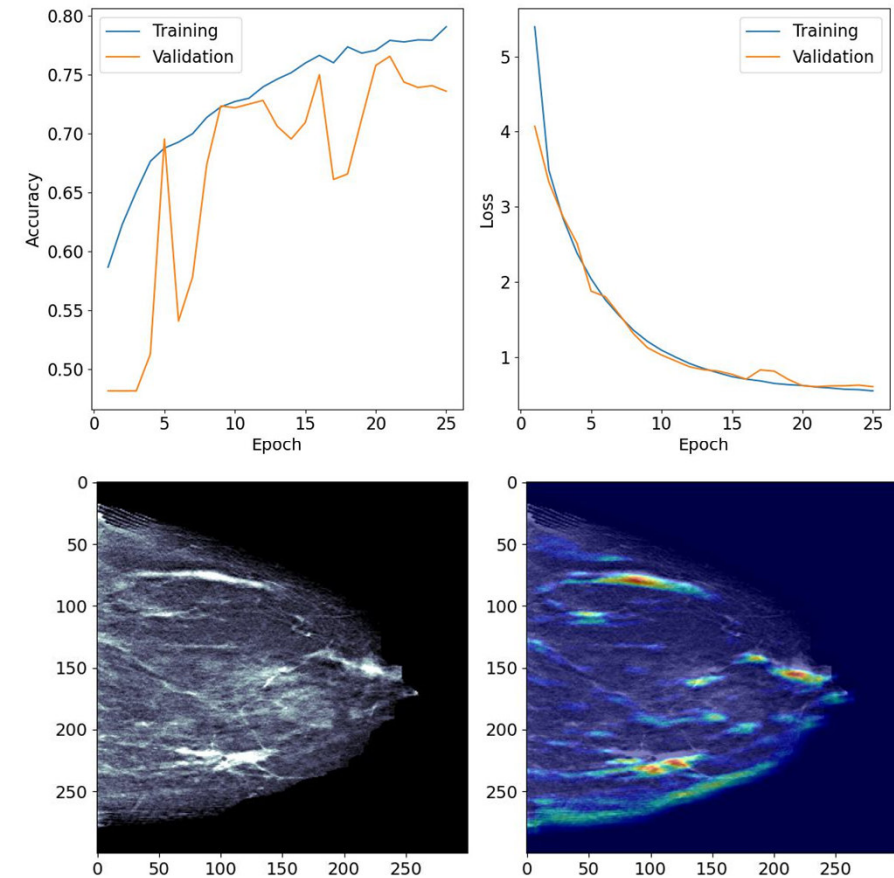

5-fold cross-validation

DL for BDT classification: results – 2 classes CC + MLO slices

ResNet18 (Transfer learning) + 1 top conv layer (for RGB2Gray) + 2 bottom dense layers.

5-fold cross-validation

DL for BDT classification: conclusions

- A tool for the classification of DBT slices has been developed.
- The tool could be useful as a template for other medical imaging classification problems.

Open issues

- Improve the classification performance of the considered models, in particular for the 3 classes problem
- Assess the ability of the classifier to correctly recognize the position of lesions (via Grad-CAM analysis)

Possible strategies for improving the performance and avoid overfitting

- Improve further the considered dataset with **more patients** (but Duke dataset contains mainly negative cases -> data imbalance)
- Implement the pre-processing in python and apply a **better data harmonization**
- Adoption of an **approach** similar to the one described in

Buda M et al. 10.1001/jamanetworkopen.2021.19100, who proposed the challenge <https://www.aapm.org/GrandChallenge/DBTex/> for which the Duke dataset was released. They trained the CNN to recognize a-priori the mass position...

Thank you for your attention...
