Particle Physics

- Radiotracer injected into the body
- Cells with abnormal metabolic behavior will show an excess of radiotracers
- Positron emission $\rightarrow e^- e^+$ annihilation
- Detect 2 back-to-back Gamma at 511 keV
- Reconstruct image from Line of Response (LoR)

Atherosclerosis plaques in mouse
Pre-clinical scanner

Murine Atherosclerosis case study

Mouse phantom derived from Digimouse PET combined with an atherosclerotic plaque from microCT data.

30 MBq Injected activity, 45 mL mouse volume while the plaque's 0.006 mL.

20 min acquisition = 1.4×10^{11} background and 8.4×10^8 signal annihilations.

Digimouse PET dataset

microCT of atherosclerotic plaque

Monte Carlo truth

Murine Atherosclerosis case study

The plaque is visible after performing axial slice of reconstructed mouse.
Timing noise is neglected (No random coincidences are present)

Monte Carlo truth

Reconstruction

Best **pre-clinical small animal** scanner combine MRI – CT with PET to achieve resolution of **0.5mm³**

Overview of current small animal PET scanners

Our proposal (MAPS)
1 order of magnitude better!

Monolithic Active Pixel Sensors
Flexible Printed Circuit
High Z absorber (orange)

How far can we
bring down the spatial resolution?

How far we can go?

No acollinearity,
No positron range,
 $p = 0.1$ mm, no bismuth,
reconstructed with OSEM

No uncertainty in Gamma emission process

How far we can go?

Positron range: 102μm FWHM for F18

Acolinearity: $90\mu m \approx 4 \cdot 10^{-3} R$

How far we can go?

100μm pixel pitch

Reference scanner

Reference scanner ~ state of the art

Positron range: 102μm FWHM for F18

Acolinearity: $90\mu m \approx 4 \cdot 10^{-3} R$

Large improvement with respect to reference scanner

Line of Response Residuals Distribution

Tower: 60 quad-module layers (240 chips)

100μPET Scanner:
4 towers (960 chips)

F. Cadoux et al.

The 100 μ PET ASIC

Specifications for the ASIC

Event size	1 cluster (< (5x5) pixels)
Event rate	10 kHz/cm ²
Equivalent Noise Charge (ENC)	~250 e ⁻
Operation Threshold	[2000 / 3000] e⁻
Time resolution RMS (Qin > 7 ke ⁻)	200 ps
ToA	Yes, seed pixel
ToT	Yes, for time-walk correction
Power consumption	< 100 mW/cm ²
Pixel pitch	150 μm

~7.2keV ~10.8keV

CMOS monolithic sensor in IHP SG13G2 BiCMOS, **130 nm** process featuring **SiGe HBT**

What are Monolith active pixel sensors ?

Analog electronics in pixel
electrode deep-nwell
(100% sensitive region)

Digital electronics placed in a separate
deep-nwell to improve noise robustness
(non-sensitive region)

LHC Application: Preshower for FASER -> [webpage](#)

High-radiation level
timing layers
for particle physics

Moderate radiation level
extremely thin
timing layers
for particle physics

Medical Application: 100μPET

NPN SiGe HBT

(depleted regions in light colors)
from wikipedia

SiGe HBT = BJT with Germanium as base material.

Grading of Ge doping in base:

- Charge-transport in base via **drift**
 - reduced charge-transit-time in base
 - high current gain β
- **High doping** in base is possible:
 - thinner base
 - reduced base resistance R_b

$$ENC_{series\ noise} \propto \sqrt{k_1 \frac{C_{tot}^2}{\beta} + k_2 R_b C_{tot}^2}$$

IHP SG13G2 technology,

Chip overview

First production wafers received in November 2024.

Electrical testing ongoing: sensor shows leakage current (no depletion),

Front-end electronics testing: normal operation

100μPET ASIC Wafer, each having 23 chips.

100μPET Probe Card (196 needles).

ASIC mounted on PCB with wire bonds.

First batch delivered in november 2024
Produced in the target 4k Ω substrate

Sensor seems to be damaged
Already at -1V bias, very high current
(>1 μ A) between substrate and wells.

Not caused by design ASIC as same failure in
appears foundry test-structure
Foundry was able to reproduce failure on
another design with same silicon
substrate

o<6>	0	0	0	0	0	0	1	1	1	1	1	1	1	0

Supercolumn independent Flash-TDC with 7-stages free-running ring oscillator.

- States of the oscillator encode the fine-time: expected **LSB = 150ps**.
- Coarse timing with a counter on stage 0 and disambiguation bit on stage 1.
- **Reference** and **Calibration's** channel signals are generated per Supercolumn.
- Reference : Synchronization with DAQ for coincidence with an internal counter at readout clock frequency (50MHz).

OFF Topic : Sub-picosecond TDC Just published

<https://doi.org/10.3390/s25175577>

Front-End timing Performance

Excellent timing performance at very low power consumption.

Want to see what SiGe can do with little increase in power consumption?

Don't miss the talk from M. Milanesio

Time resolution with not-calibrated Testpulse

$\sigma = 60$ ps

$\sigma = 263$ ps

$\sigma = 1863$ ps

Expected input charge from MC simulation: $15 \text{ ke}^- \pm 3 \text{ ke}^-$
Discriminator working point not optimized for timing (10% of the design power consumption).

Good time resolution to select
coincidence events from noise

Use 1 ns time window
“4D-Tracking”

Gaussian smearing to time stamps.
Timing standard deviation of 700 ps.
Optimal coincidence time window
found between
1 and 2 ns.

$$\text{NECR} = \frac{Tr^2}{Tr + Sr + Rr}$$

The improved timing resolution and granularity of MAPS used in 100μPET enable

- Total timing jitter of $\sigma_{\text{time}} = 700$ ps
- Coincidence window $\tau_{\text{win}} = 2$ ns

No signs of NECR saturation compared to Hyperion II^D.

Mismatch and threshold tuning

$$N_R = f_{n0} \cdot e^{\frac{-Q_{th}^2}{2 \cdot ENC^2}}$$

Mismatch worsens the Noise Rate. With threshold tuning, we can achieve the required Noise Rate

Mismatch and threshold tuning

Mismatch worsens the Noise Rate. With threshold tuning, we can achieve the required Noise Rate

First Attempt of Threshold Tuning

S-Curve before threshold tuning with injected charge

S-Curve after threshold tuning with injected charge

The 100μPET Scanner has the potential to deliver ultra-high resolution imaging using MAPS thanks to:

Detection Efficiency at 4.4 %

PSF resolution < 300 μm

Volumetric spatial resolution of 0.02 mm³
