Supervisor: Costas Vellidis

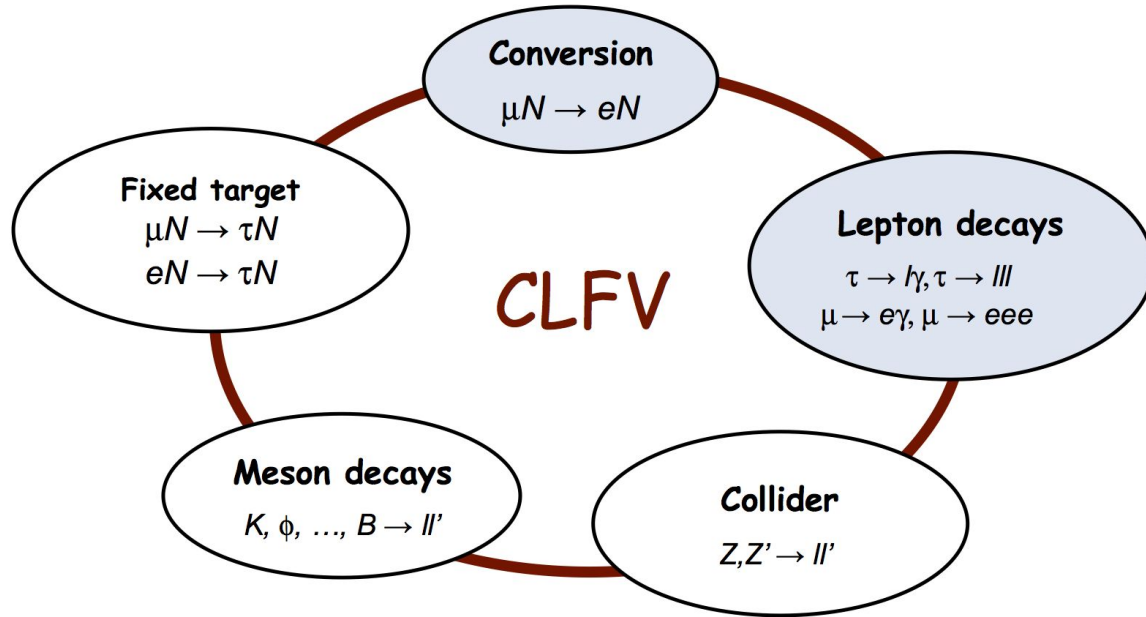

Università di Milano

Table of contents

- Mu2e experiment and CLFV
- Previous study of TS misalignments
- Purpose of my study
- Results and discussion

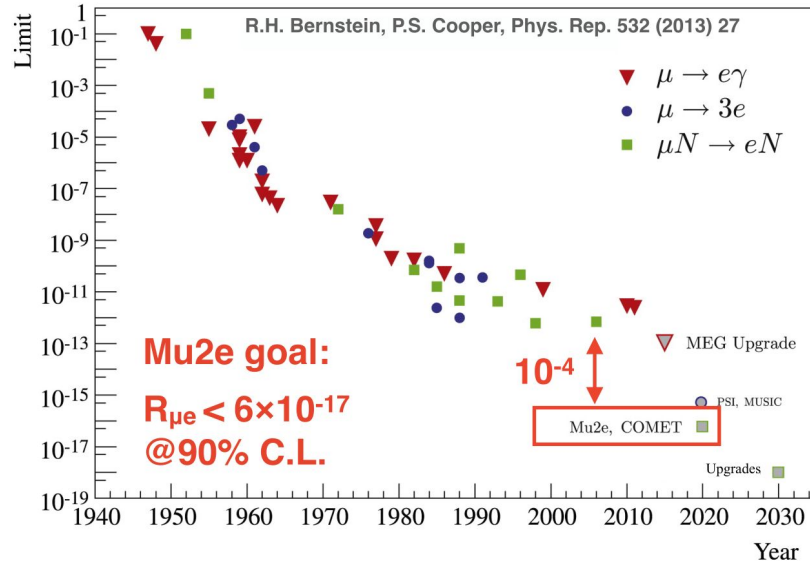

Charge Lepton Flavor Violation (CLFV)

- In the Standard Model (SM) neutrinoless charged lepton decays are extremely suppressed ($< \sim 10^{-52}$)
- Therefore observation of such decays is a signature of new physics

- Muons offer the best signatures because they are easily produced and weakly decaying, with a long τ_3

CLFV history

$$\mu \rightarrow e\gamma$$

$$(BR < 10^{-13})$$

Evidence of physics beyond the Standard Model

$$(BR < 10^{-52})$$

- Mu2e search process: conversion of muon into electron in a field of a nucleus, $\mu N \rightarrow eN$

Why?

- Muons are easy to produce and have a lifetime long enough to make muonic atoms
- Best combination of new physics reach and experimental sensitivity

Mu2e in a nutshell

1. Produce 10^{18} muonic Al atoms in the 1s state after 3 years of running
2. Count “muon conversion electrons” with tracking and calorimetry
 - Mono-energetic electrons emanating from the Al target

$$E_e = m_\mu - E_b - E_{recoil} = 104.96 \text{ MeV}$$

3. Suppress Background

➤ What happens to Muonic Al?

- Nuclear capture ($\sim 61\%$) → **Normalization factor**
- Muon decay in orbit (DIO) ($\sim 39\%$) → **Main Background**
- Muon to electron conversion ($< 10^{-13}$) → **Signal**

Mu2e outlook

- Pions are produced and decay into muons which spiral in the Transport Solenoid (TS)
- $3 \cdot 10^{20}$ protons at the production target
- Single Event Sensitivity:

$$R_{\mu e} = \frac{\mu^- + A(Z, N) \rightarrow e^- + A(Z, N)}{\mu^- + A(Z, N) \rightarrow \nu_{\mu}^- + A(Z - 1, N)} \simeq 3 \cdot 10^{-17}$$

Transport Solenoid

- “S” shape → to select only charged particles
- 3 Collimators → TS3 selects negative particles because they drift above the horizontal plane

Studies of the physics effects of TS misalignments have already been made (F. Bradascio, MSc thesis Mu2e-doc-7808)

My work focuses on physics effects of the misalignments of the central collimator (TS3) along the TS beamline

Methodology and topics

- All the work presented here is done using the Mu2e default map: Mau10
- Physics simulation with GEANT4 in the framework of the Mu2e offline software
- Only the actual geometry is varied, not the field
- Analysis is conducted in ROOT

Topics examined

- **Muon and Pion Stopping Rates**
 - The muon capture and pion absorption probabilities at the stopping target depend on the direction of these particles, determined by the TS field
- **Background from Beam Electrons**
 - The scattering probability of beam electrons off the stopping target material depends on the direction of the electrons, determined by the TS field
- **β Source Test**
 - We can approximately trace the TS field lines by taking advantage of the small Larmor radius of low-momentum electrons injected into TS from a conventional β source

My work plan

Study only displacements and rotations of TS3 collimator:

Why is it important?

- Hole in the upper part selects negative particles with appropriate momentum → possible misalignment affects charge and momentum range selection
- What can happen to the physics of the experiment with slightly wrong momentum range and charge selection?

80+80 cm long Cu

My work plan

Enormously exaggerated misalignments, to test the induced effects

Displacement:
2 cm up, 2 cm down

Rotation:
15° right, 15° left

Steps:

- A. Shift up 2 cm
- B. Shift down 2 cm
- C. Rotation right 15°
- D. Rotation left 15°

Topics:

- Muons and Pions stopping rates
- Beam electrons
- Beta source test

Stopping Rates

Simulation provides the transport of muons and pions from the production target up to the stopping target

Protons on target: 10 M → muons can decay

→ pions are forced to be stable

Because of their shorter lifetime

➤ Estimation of background: Muon stopping rate: $\frac{N_\mu}{N_{POT}}$

Pion stopping rate: $\frac{n_\pi}{N_{POT}}$

n_π = number of pions weighted by $e^{-t/\tau}$
 τ = pion lifetime of 26 ns

➤ Deviation in rate between default case and rotated field maps

- Fractional yield factor:

$$\alpha = \frac{Y_{varied} - Y_{default}}{Y_{default}}$$

$$\delta_\alpha = \sqrt{\frac{Y_{varied} \cdot (Y_{varied} - Y_{default})}{Y_{default}^3}}$$

$Y = N$ for muons
 $Y = n_\pi^\mu$ for pions

Muons and pions stopping rates

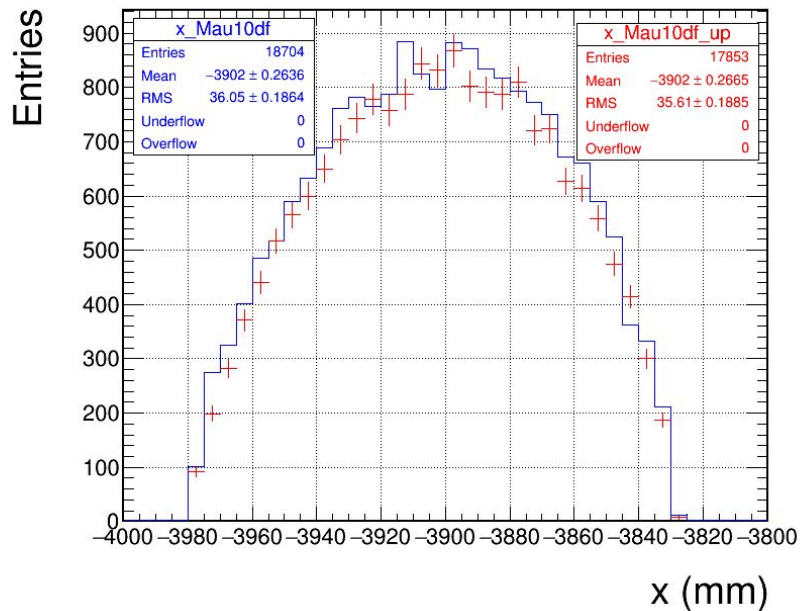

- Displacements:
 - Decrease of statistics moving the collimator: mainly a geometric effect
 - The weighed pion rate is very low (a few pions stopped) to allow significant conclusions
- Rotations:
 - Consistent results as we expected → rotation doesn't affect spiraling particles

→ Fractional yield differences: more sensitive to displacement down

	α_{μ} [%]	α_{π} [%]	N_{μ}/N_{POT} [10^{-3}]	n_{π}/N_{POT} [10^{-7}]
Default	----	----	1.87 ± 0.01	6.27 ± 0.08
UP (2cm)	-4.55 ± 1.00	12 ± 61	1.79 ± 0.01	7.01 ± 0.09
DOWN (2cm)	-7.18 ± 0.98	-17 ± 49	1.74 ± 0.01	5.18 ± 0.07
Right (-X 15°)	-0.98 ± 1.03	2 ± 57	1.85 ± 0.01	6.40 ± 0.08
Left (+X 15°)	-0.47 ± 1.03	4 ± 58	1.86 ± 0.01	6.53 ± 0.08

A) Muons shifted up

X of μ^- stop

Y of μ^- stop

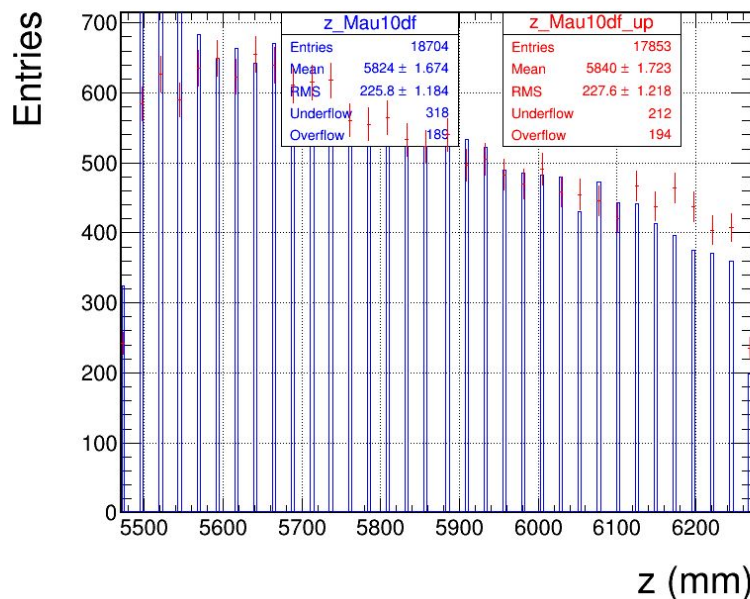

- Comparison with Federica results for the default case:
- Y distribution differs by many sigmas from the default case in accordance with the shift

Mean X	-3902.0 ± 0.8
Mean Y	3.8 ± 0.8

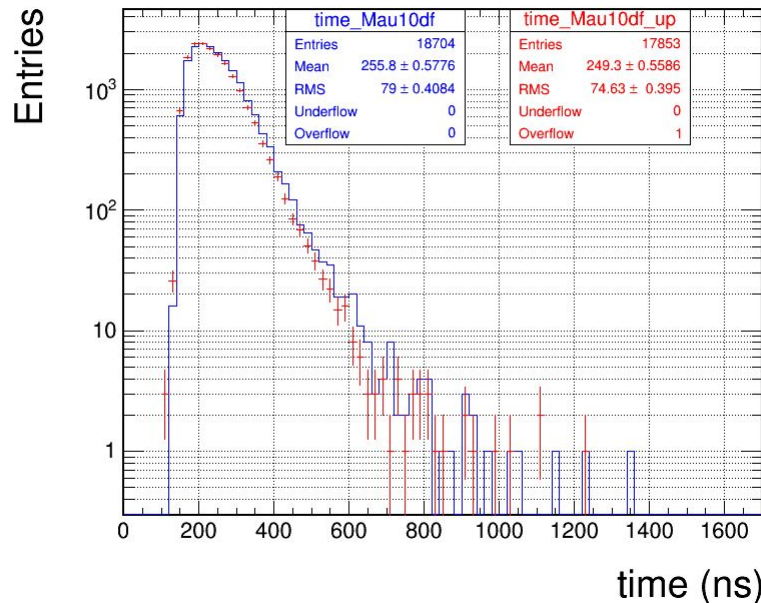

A) Muons shifted up

Z of μ^- stop

- Comparison with Federica results:

Time of μ^- stop

Mean Z	5814 ± 5
Mean time	256 ± 1

Beam electrons background

- Proton Beam: $2 \cdot 10^9$ POT produces $\sim 100 e^-$ arriving at the stopping target (VD9) → resampling needed to increase statistics (resampling factor = 10^6)
 - A second stage simulation using the resampled e^- as input provides momenta and locations of e^- hits in the tracker volume
- Results have big statistical fluctuation in number of e^- at the tracker
- **crude approximation:** could be done more efficiently by resampling over the cross section

Background Estimation:

$$N_e = \frac{N}{N_{stat}} \times 3 \cdot 10^{20} \times 10^{-10} \times 0.5 = (2.5 \pm 1.2) \times 10^{-4}$$

By Federica Bradascio

N = number of electrons in tracker that have $104 < P < 106$ MeV/c and $0.4 < P_z/P < 0.7$

N_{stat} = number of simulated POT times resampling factor (10^6)

3×10^{20} = expected number of POT in the experiment

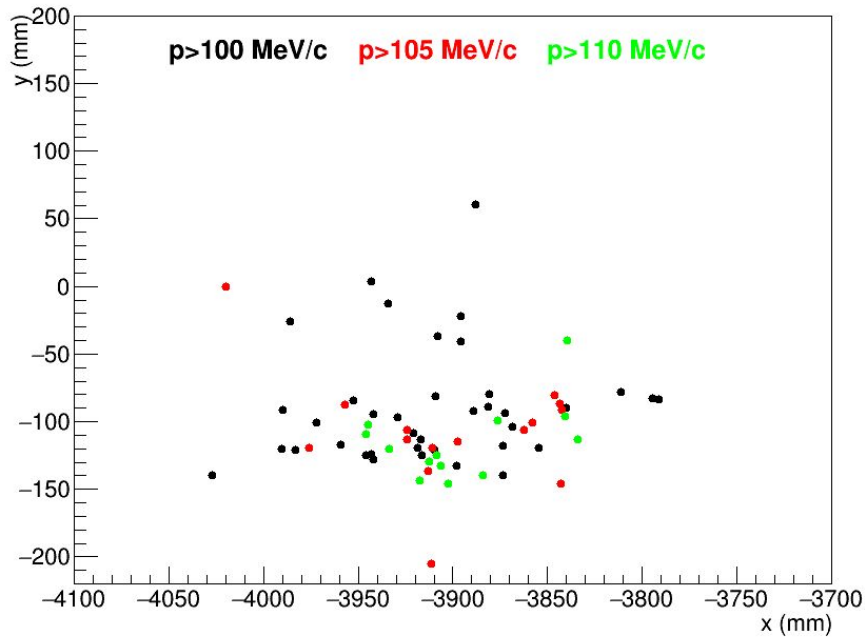

10^{-10} = extinction factor

0.5 = live time window

Default case: first stage

- Collect electrons at VD9 → POT: 2.0 M, e at VD9: 66
- Selected e^- with $p > 100$ MeV

(X,Y) distribution at VD9

- hits in the downstream part because of the field lines:

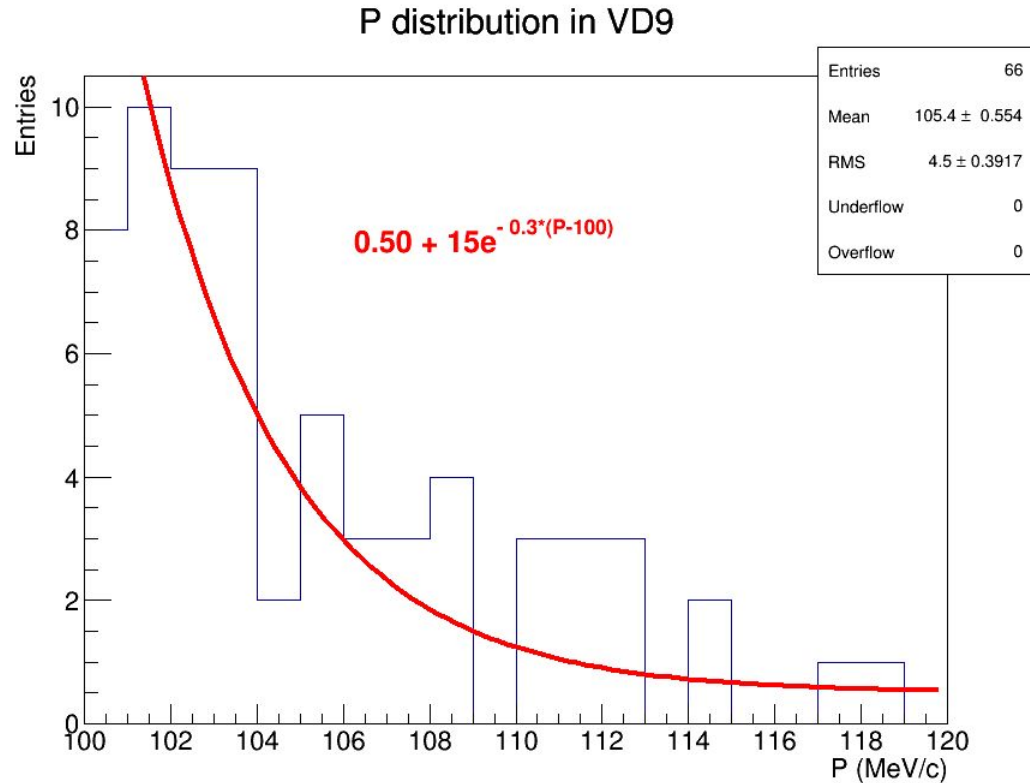

Default case: Momentum distribution

- Fit the momentum distribution in order to do the resampling → particle momenta are randomized according to this fit
- Position and time distributions are randomized according to a gaussian distribution with $\sigma=10$ mm and $\sigma=10$ ns
- Momentum distribution: $f(p) = A e^{-k(p-p_0)}$

Federica's result: $(81 \pm 9) e^-$ at VD9

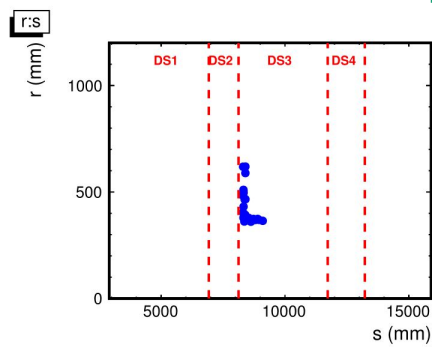

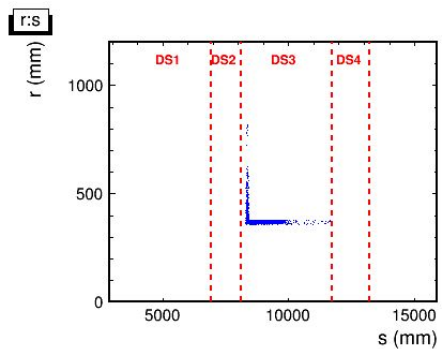

My result: $(66 \pm 8) e^-$ at VD9

Default case: Distribution of e^- hits in the tracker volume

Cut: $p > 95$ MeV/c

After cuts:
 $104 < p < 106$ MeV;
 $0.4 < p_z/p < 0.7$

Comparisons and Background

	original e ⁻	e ⁻ VD9	e ⁻ tracker before cuts	e ⁻ tracker after cuts	Background
Default Mau10	1997 ± 45	66 ± 8	6717	26	(2.0 ± 0.6) × 10 ⁻⁴
up	2000 ± 45	225 ± 15	18531	118	(9 ± 1) × 10 ⁻⁴
down	1996 ± 45	22 ± 5	4745	40	(3.0 ± 0.3) × 10 ⁻⁴
Right 15°	2000 ± 45	90 ± 10	5548	25	(1.9 ± 0.7) × 10 ⁻⁴

- Consistent results with previous studies for default case: → Federica's: (1.9 ± 0.1) 10⁻⁴
- The only case where the estimated background changes significantly is the displacement up
- This is expected because electrons drift higher up than muons in the TS3 region, due to a higher velocity distribution corresponding to the same momenta (→ same Larmor radii)

Beta source test

We cannot measure the field inside TS, so we need a sensitive test of TS misalignments: this can be done using low momentum electrons

- Source: $^{90}\text{Sr}/^{90}\text{Y}$ - No background
- "Virtual detector": - Good momentum range
 - (X,Y) resolution: $\sim 300 \mu\text{m}$
 - Momentum threshold: 200 keV/c
- 1 Torr air pressure is assumed in the beam line, to ensure that the electrons go through
- For each misalignment, 27 source positions are examined
- Look only at VD3 and VD4 because the TS3 cut is applied between them

Comparison between default, up and down: steps of 50 mm

Conclusions

- In general, only the up and down shifts and only in some cases can impact significantly the physics parameters of the experiment; rotations do not play an important role.
- Stopping rates: up and down shifts are important due to a geometric effect → the beam arriving at the stopping target is significantly displaced by the shifts.
- Beam electrons background: sensitive to collimator misalignments, increases as the collimator is shifted upwards → electrons drift higher up than muons in TS3.
- Beta source test: sensitive to collimator shift up → after the collimator the spots are cut and the corresponding $\langle Y \rangle$ is shifted up.
- The above findings for largely exaggerated misalignments of the TS3 collimator guarantee that the collimator design provides a safe operation point for the experiment.

Thank you for the attention
