The short-baseline neutrino project (SBN) includes three Liquid Argon Time Projection Chamber detectors (LAr-TPCs) located on-axis in the Booster Neutrino Beam (BNB) at Fermilab

SBN PROJECT

Detector	Distance	LAr Total mass	LAr Active mass
SBND	110 m	220 ton	112 ton
MicroBooNE	470 m	170 ton	89 ton
ICARUS-T600	600 m	760 ton	476 ton

TPC Parameter

Value

Active volume Number of TPC cells Structure Maximum drift time 5 m x 4 m x 4 m, 112 ton active LAr 2 drift volumes, 2 m drift length each 2 Anode planes and 1 Cathode plane $1.28 \ \mu s$ Measurements that can be performed with SBND:

SBND will be able to discriminate a single-electron or single-photon in the final state, thing that LSND and MiniBooNE couldn't do. They had anomalies at low energy due to to an electron-like excess events. This is important for oscillation measurement.

(Electron (left) and gammas (right) electromagnetic showers in liquid argon)

- Precise neutrino-nucleus cross-sections measurement, e.g.:
 - ν_µ charged-current 0 pion final state event sample will allow the study of nuclear effects in neutrino interactions in argon nuclei.
 - Charged-current event sample will allow ν_e CC and ν_μ CC cross sections measurement. Comparison will test lepton universality.
 - Elastic scattering events ν_μe → ν_μe will allow a measurement of sin²θ_W.

Section 1: Neutrino elastic scattering events selection

Section 2: Neutrino charged-current 0π expectation

Section 3: Neutrino charged-current 1π expectation

Section 1: Neutrino elastic scattering events selection

Flux measurement with the highest precision possible for the Booster Neutrino Beam (BNB) through the neutrino elastic scattering interaction because of its well known cross section

Booster Neutrino Beam is produced at Fermilab, in neutrino mode its composition is reported in the plot

8/22

Signal

GENIE simulation for SBND active volume Simulation run: $6.6 \cdot 10^{20}$ POT (3 years)

Uncertainty on flux is one of the highest in neutrino experiments. Short distance allows really high event rate and no oscillation signal, perfect condition for flux measurement.

Process: Elastic scattering

$$u_\mu \ { extbf{e}}^-
ightarrow
u_\mu \ { extbf{e}}^- \qquad (92.3\%)$$

 $\begin{cases} \nu_{e} e^{-} \rightarrow \nu_{e} e^{-} & (4.4\%) \\ \overline{\nu}_{\mu} e^{-} \rightarrow \overline{\nu}_{\mu} e^{-} & (2.5\%) \\ \overline{\nu}_{e} e^{-} \rightarrow \overline{\nu}_{e} e^{-} & (0.2\%) \end{cases}$

Irriducible background. Consider all of them as signal and weight the events according to the cross sections

Elastic scattering cross section

$$\begin{split} \sigma_{\nu_{e}e \to \nu_{e}e} &= \frac{G_{F}^{2}s}{\pi} \left[\left(\frac{1}{2} + \xi \right)^{2} + \frac{1}{3}\xi^{2} \right] = 9.5 \cdot 10^{-49} m^{2} (E_{\nu} / 1 \text{MeV}) \\ \sigma_{\overline{\nu}_{e}e \to \overline{\nu}_{e}e} &= \frac{G_{F}^{2}s}{\pi} \left[\frac{1}{3} \left(\frac{1}{2} + \xi \right)^{2} + \xi^{2} \right] = 4.0 \cdot 10^{-49} m^{2} (E_{\nu} / 1 \text{MeV}) \\ \sigma_{\nu_{\mu}e \to \nu_{\mu}e} &= \frac{G_{F}^{2}s}{\pi} \left[\left(\frac{1}{2} - \xi \right)^{2} + \frac{1}{3}\xi^{2} \right] = 1.6 \cdot 10^{-49} m^{2} (E_{\nu} / 1 \text{MeV}) \\ \sigma_{\overline{\nu}_{\mu}e \to \overline{\nu}_{\mu}e} &= \frac{G_{F}^{2}s}{\pi} \left[\frac{1}{3} \left(\frac{1}{2} - \xi \right)^{2} + \xi^{2} \right] = 1.3 \cdot 10^{-49} m^{2} (E_{\nu} / 1 \text{MeV}) \\ \xi = \sin^{2}\theta_{W} \\ g = (P_{\nu} + P_{e})^{2} \simeq 2m_{e}E_{\nu} \end{split}$$

Background

Events with only an e⁻ detected in final state

Candidates: Charged channel

```
\nu_e \ \mathrm{N} 
ightarrow \mathrm{e}^- \ \mathrm{Op} \ \mathrm{O}\pi
```

NOTE: Proton with less than 21*MeV* kinetic energy is not reconstructed in detector (ArgoNeuT)

For 6.6 · 10²⁰ POT:

```
Elastic scattering: 401 events (373 \nu_{\mu}, 18 \nu_{e}, 10 \overline{\nu}_{\mu})
Background: 4534 events
S/B \simeq 0.08
```

Need a way to select signal from background, kinematic variable selection

ArgoNeuT proton discrimination

Background events are due to CC 0p 0π only because with liquid argon technology it's possible to detect protons at main vertex (clockwise from upper left corner: 0 proton, 1 proton and 2 protons events at vertex)

Kinematic expectation: Momentum distribution

Momentum is not an efficient variable for a cut selection (left: elastic scattering events, right: CC 0p 0π events)

Kinematic expectation: Angle distribution

Angle alone can't be a reasonable choice even though the separation is more evident (left: elastic scattering events, right: CC 0p 0π events)

Cut selection

Separation gets evident combining the two: $E \cdot \theta^2$

Possible cut (numbers in brackets includes irreducible background from elastic scattering) $\begin{cases} 0.003 \text{ GeV rad}^2 \colon 57(85) \text{ background events } (S/B = 7.0(4.4)) \\ 0.004 \text{ GeV rad}^2 \colon 75(103) \text{ background events } (S/B = 5.3(3.6)) \end{cases}$

Section 2 and 3: Charged-current events

Neutrino beams are not mono-energetic, multiple processes at a given E_ν

Since ν -experiments use nuclear targets, in the GeV ν -energy range the most important neutrino-nucleus interaction channel is the CC quasi elastic scattering (QE), but nuclear effects play a key role \rightarrow intra-nuclear-scattering In QE interaction nucleons, γ and π can be found in final state.

Full 3D imaging, calorimetric energy reconstruction and particle identification

CC neutrino events can be classified in terms of final state topology based on particle multiplicity

With this type of detector is possible to measure kinematic distributions for all the particles in final state

Estimated events rate using GENIE in SBND active volume for $6.6 \cdot 10^{20}$ POT, a 21 MeV kinetic energy threshold is assumed on protons. No restriction on number of neutrons is made for the table.

Clockwise from upper left corner: proton multiplicity for ν_{μ} CC 1π events, proton multiplicity for ν_{e} CC 1π events, π^{+} angle in CC 1π events, π^{+} energy in CC 0π events

Conclusions

Precise neutrino-nucleus cross section measurements are a fundamental prerequisite for every neutrino oscillation experiment, including the future LAr long-baseline neutrino program.

The SBND detectors will collect neutrino samples with high statistics and will make the world's best measurements of ν_{μ} -Ar and ν_{e} -Ar scattering, including rarer processes such as ν -e scattering, strange particle production, multi-nucleon and multi-pion production, and coherent scattering with an argon nucleus.
