

Vertex Track Performance Studies

Giacomo Ubaldi

XIV FOOT Collaboration Meeting

Bergamo

06/06/2023

- Performance studies applied on **MC GSI 2021** campaign
- Data-taking at GSI (Darmstadt, Germany) in 2021
- ^{16}O 400 MeV/u on 5 mm **C target**
- Partial setup: no magnet, only one module of calorimeter

Definitions for performance factors

- **Reference set: $N_{\text{reference}}$** (truth side)
all the tracks that an algorithm performing ideally should find and reconstruct:
 - all the tracks associated to a MC particle that crosses the FOOT apparatus at least until the last plane of the vertex (using MCRRegion)
 - beam
 - primary fragment generated in the target
- **Good reconstructed set: N_{GoodReco}**
all the tracks that are reconstructed by the tracking algorithm which are associated to MCparticles in the reference set .
- **Bad reconstructed set: N_{BadReco}**
all the tracks that are reconstructed by the tracking algorithm but associated to MC particle that do not belong to the reference set.

Track reconstruction

For the track reconstruction I considered:

case 1: a track is reconstructed with 4 clusters (one for each VT plane)

case 2: a track is reconstructed with at least 3 clusters

case 3: a track is reconstructed with at least 3 clusters + random noise pixels are generated

NB:

To associate a MC Particle to a reconstructed track:

- I consider the MC ID of all the clusters belonging to the track
- I take the most frequent one: this is the ID of the MC Particle matched

Performance factors

- **Reconstruction efficiency:**

Efficiency of reconstructed tracks

- elemental efficiency higher than 0.9 for $Z \geq 2$, close to 1 for $Z \geq 3$

$$\epsilon_{track}(Z) = \frac{N_{GoodReco}(Z)}{N_{reference}(Z)}$$

tracks with 4 clusters (case 1)

tracks with ≥ 3 clusters (case 2)

tracks with ≥ 3 clus + noise (case 3)

FIRST vertex efficiency:

Table 2

Tracking efficiencies and associated errors for different charge values of detected particles (simulated data).

Z	1	2	3	4	5	6
Efficiency (%)	93.6	88.9	97.5	97.7	98.8	99.9
Error (%)	0.3	0.6	0.7	0.8	0.4	0.1

Nuclear Instruments and Methods in Physics Research A 767 (2014) 34–40

Performance factors

- **Purity:**

Purity of reconstructed tracks out of the selected ones

- elemental purity higher than 0.8, it decreases with heavier Z

$$p_{track}(Z) = \frac{N_{GoodReco}(Z)}{N_{GoodReco}(Z) + N_{BadReco}(Z)}$$

tracks with 4 clusters (case 1)

tracks with ≥ 3 clusters (case 2)

tracks with ≥ 3 clus + noise (case 3)

Performance factors

- **Multiplicity:** n° of different clusters MC_ID associated to a given track

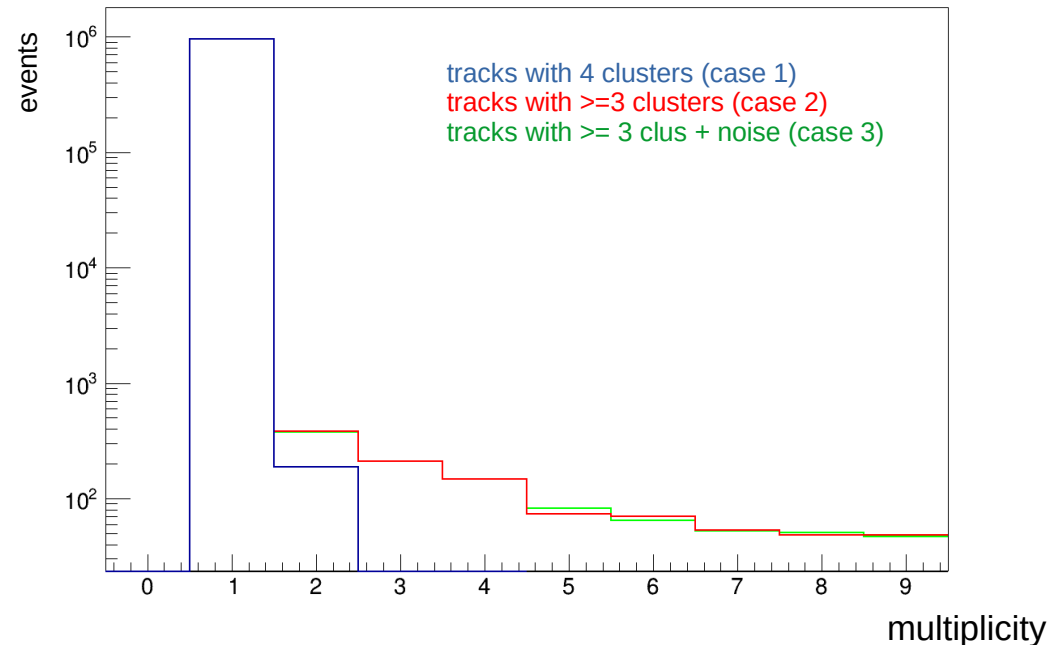

- es: m=1 all clusters are of the same MC particle
- es: m=2 clusters belong to two different MC particle (1-3,2-2)

NB: multiplicity can be higher than 4 (despite the clusters are at max 4) because every one can be associated to different MC particles (with different MC_ID)

Vertex - Track multiplicity of clusters when there is fragmentation (MC)

Vertex - Track multiplicity of clusters if no fragmentation (MC)

Performance factors

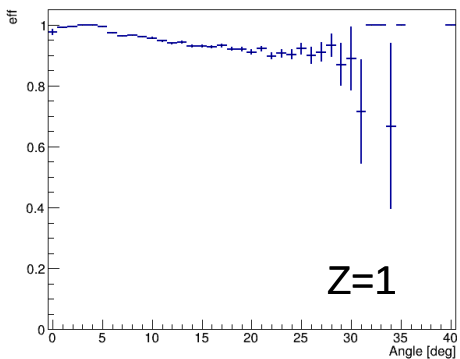

- **Angular efficiency:**

tracks with ≥ 3 clus + noise (case 3)

$$\epsilon_{track}(Z, \theta) = \frac{N_{GoodReco}(Z, \theta)}{N_{reference}(Z, \theta)}$$

- angular efficiency decreases with angle $> 10^\circ$

Angular Efficiency of reconstructed tracks for Z= 1

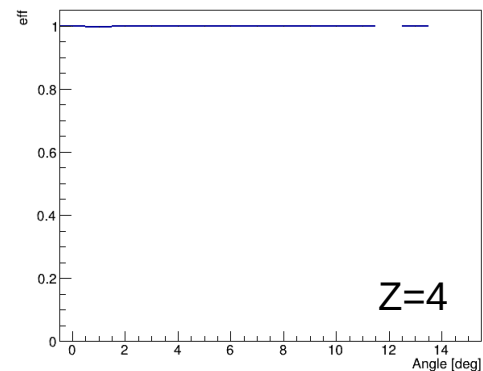

Angular Efficiency of reconstructed tracks for Z= 2

Angular Efficiency of reconstructed tracks for Z= 3

Angular Efficiency of reconstructed tracks for Z= 4

Angular Efficiency of reconstructed tracks for Z= 5

Angular Efficiency of reconstructed tracks for Z= 6

Angular Efficiency of reconstructed tracks for Z= 7

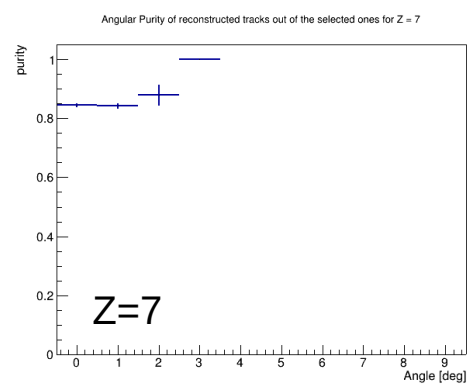

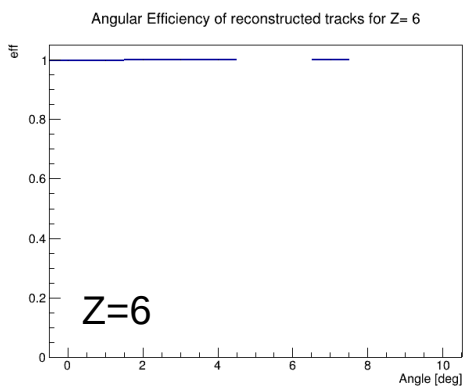

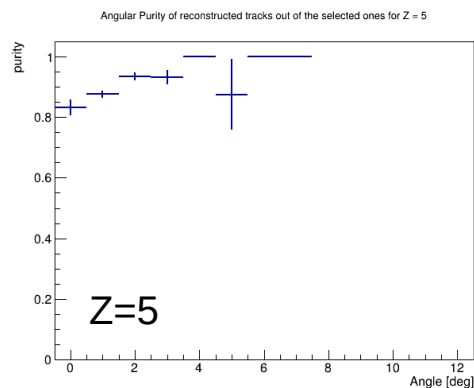

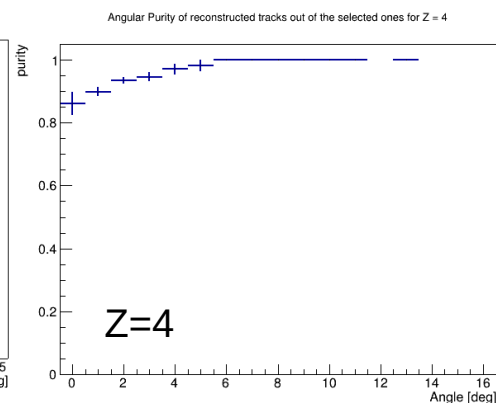

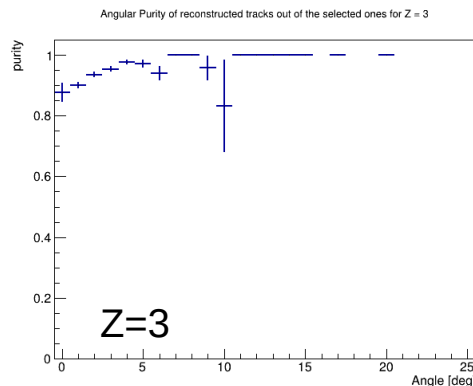

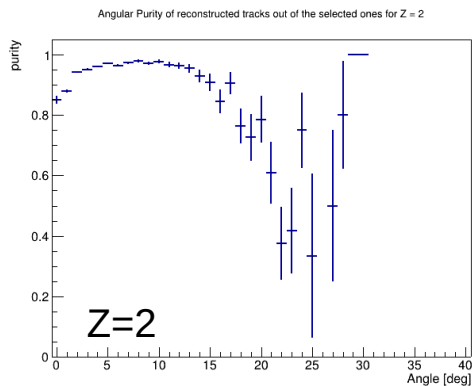

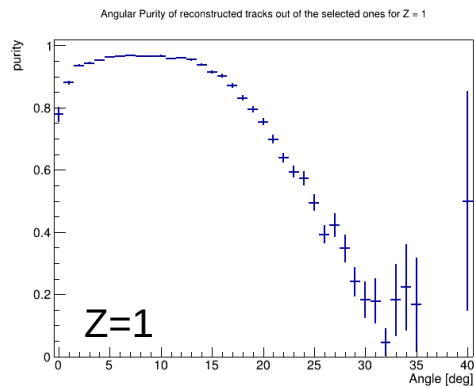

Angular Efficiency of reconstructed tracks for Z= 8

Performance factors

- **Angular Purity:** tracks with ≥ 3 clus + noise (case 3)
- angular efficiency decreases with angle $> 10^\circ$

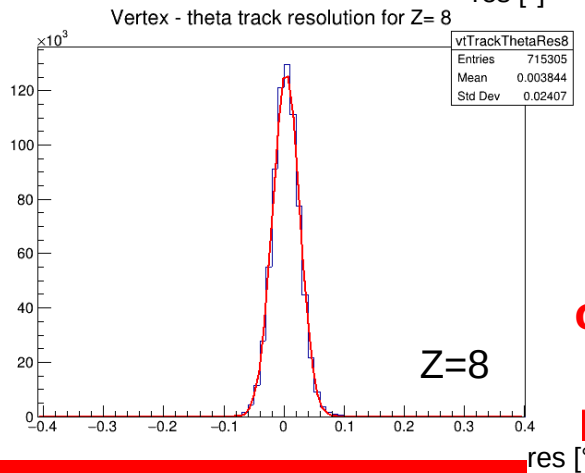

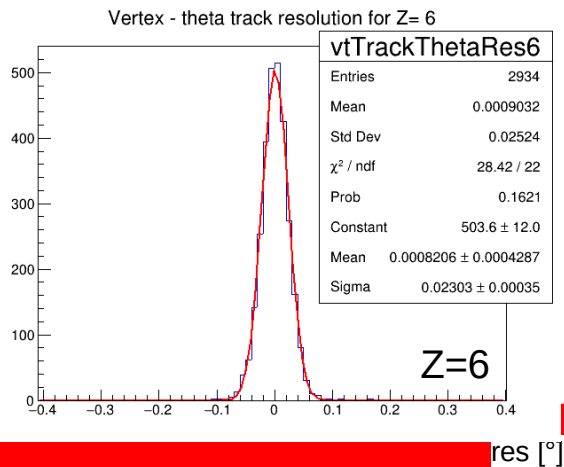

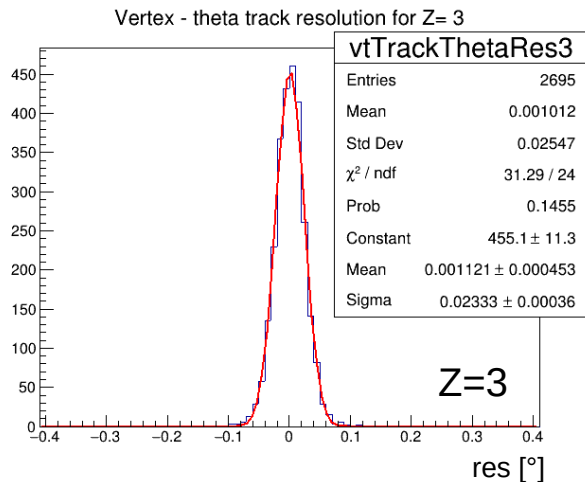

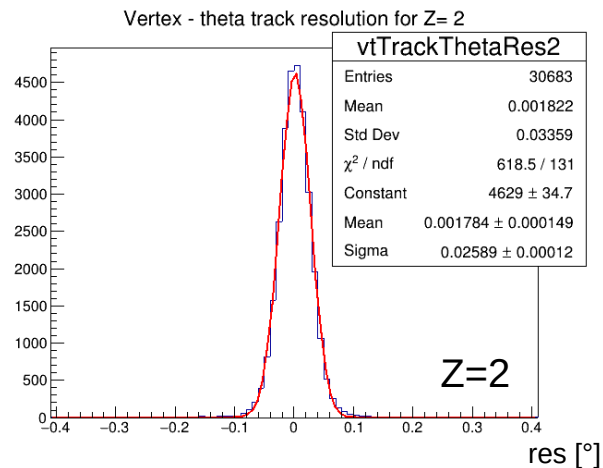

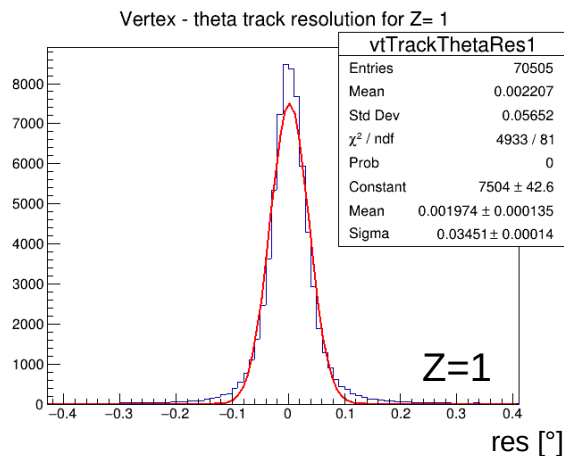

$$p_{track}(Z, \theta) = \frac{N_{GoodReco}(Z, \theta)}{N_{GoodReco}(Z, \theta) + N_{BadReco}(Z, \theta)}$$

Resolution Measurements

Track Polar Resolution

Polar angle resolution of the reconstructed track vs the mc particle: $res_{\theta} = \theta_{track} - \theta_{MCparticle}$

$\sigma \sim 0.02^\circ$

Track – Cluster position Resolution

Position resolution of the reconstructed cluster of a track vs the MC Hit (from which the cluster is generated) for every sensor of the vertex in X and Y

Vertex -Position X resolution of the cluster of sensor 1

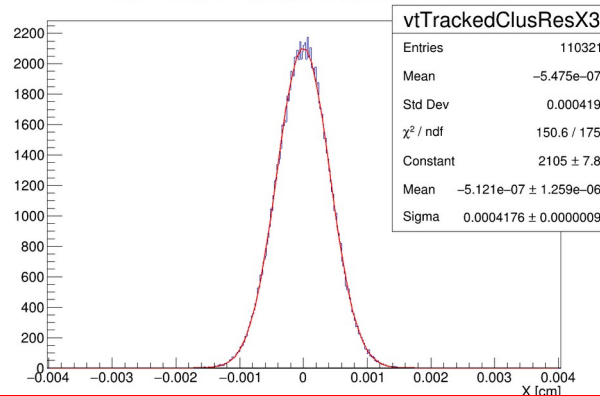

Vertex -Position X resolution of the cluster of sensor 2

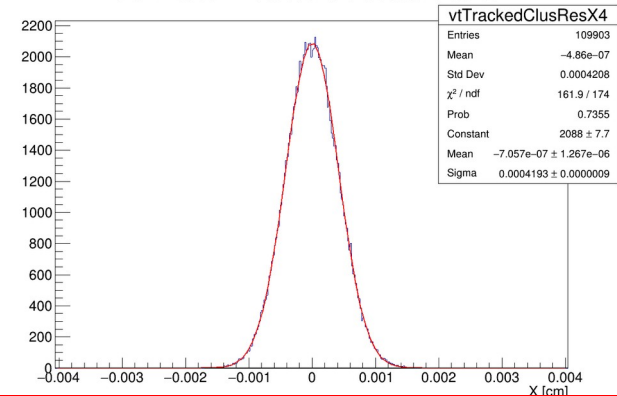

$$res_X = X_{cluster} - X_{MChit}$$

$$\sigma \sim 4 \mu\text{m}$$

Vertex -Position X resolution of the cluster of sensor 3

Vertex -Position X resolution of the cluster of sensor 4

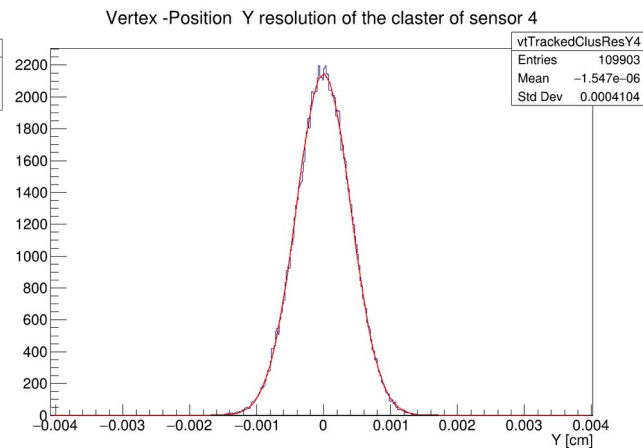

Track – Cluster position Resolution

Position resolution of the reconstructed cluster of a track vs the MC Hit (from which the cluster is generated) for every sensor of the vertex in X and Y

$$res_Y = Y_{cluster} - Y_{MCHit}$$

$$\sigma \sim 4 \mu\text{m}$$

Vertex position Resolution

Position resolution of the reconstructed vertex of tracks vs the MC fragmentation position

$$res_X = X_{vtx} - X_{MC}$$

$\sigma \sim 6 \mu\text{m}$

$$res_Y = Y_{vtx} - Y_{MC}$$

$\sigma \sim 6 \mu\text{m}$

$$res_Z = Z_{vtx} - Z_{MC}$$

$\sigma \sim 50 \mu\text{m}$

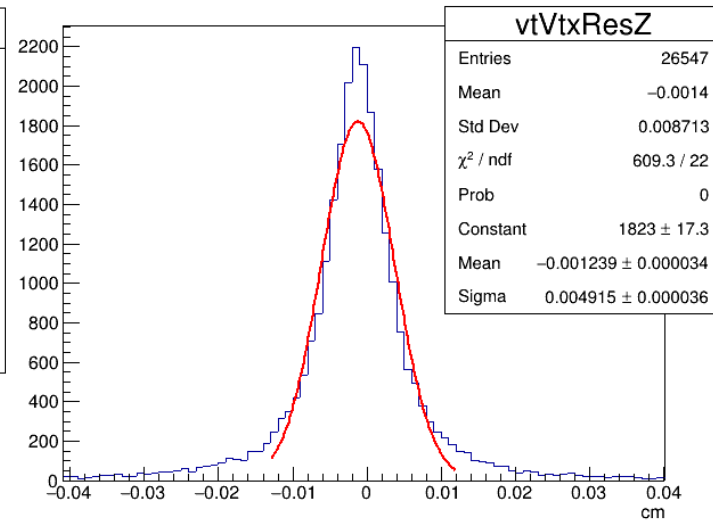

Vertex resolution at X

Vertex resolution at Y: cm

Vertex resolution at Z

Conclusions

- Good efficiencies over ~90% and purities over ~80%
 - Spatial resolution at the order of ~ μm
 - good vertex identification, fundamental for out of target fragmentation removal
 - performances in agreement with already published results.
-
- Performance studies to be run on every campaign

Thanks to Marco and Chris for the assistance and help!

Performance factors

- **Cluster purity**

counts of all the clusters matched well with the track MC_ID (in reference set)
among all clusters of all N_{GoodReco} tracks

$$\rho = \frac{\sum_{m=0}^M N_{\text{correct}}^{(m)}}{\sum_{m=0}^M N_{\text{total}}^{(m)}}$$

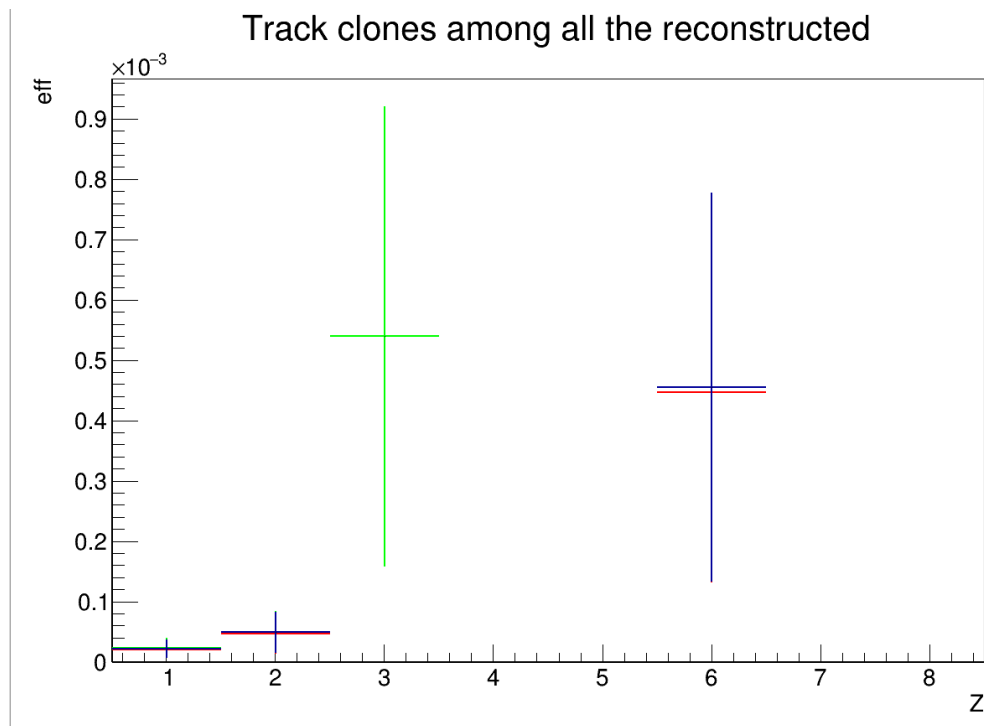

tracks with 4 clusters (case 1)
tracks with ≥ 3 clusters (case 2)
tracks with ≥ 3 clus + noise (case 3)

Definitions for performance factors

- **Clone multiplicity**

quantification of the number of multiple cloned trajectories produced for the same MC particle matched to the track

tracks with 4 clusters (case 1)
tracks with ≥ 3 clusters (case 2)
tracks with ≥ 3 clus + noise (case 3)

Vertex track angular distribution

Vertex - Track polar distribution

Vertex - Track azimuthal distribution

efficiency resolution

- I consider the selection of an event of a given Z and theta as distributed with a binomial distribution

$$P(N_{sel}|N_{tot}, \epsilon) = B(n; N_{tot}, \epsilon)$$

- A good estimator of the efficiency is $\hat{\epsilon} = \frac{N_{sel}}{N_{tot}}$

- The associated error is $\sigma_{\hat{\epsilon}}^2 = V[\hat{\epsilon}] = V\left[\frac{N_{sel}}{N_{tot}}\right] = \frac{V[N_{sel}]}{N_{tot}^2} = \frac{N_{tot}\epsilon(1-\epsilon)}{N_{tot}^2}$

then

$$\sigma_{\hat{\epsilon}} = \sqrt{\frac{\epsilon(1-\epsilon)}{N_{tot}}}$$

N reference

- **Reference set:** $N_{\text{reference}}$ (truth side)
all the tracks that an algorithm performing ideally should find and reconstruct:
 - all the tracks associated to a MC particle that crosses the FOOT apparatus at least until the last plane of the vertex (using MCRRegion)
 - beam
 - primary fragment generated in the target

```
if (
    (particle_ID == 0 // if the particle is a primary OR
    || (Mid == 0 && Reg == target_region) // if the particle is a primary fragment born in the target
    ) && particle->GetCharge() > 0 &&
    particle->GetCharge() <= primary_charge && // with reasonable charge
    OldReg == last_vtx_plane_region && NewReg == RegAirAfterVtx // it crosses the last plane of the vertex
)
return true;
```
