

Search of DM annihilation in Stellar Streams with the Fermi LAT

Cristina Fernández-Suárez

In Collaboration with Miguel Á. Sánchez-Conde

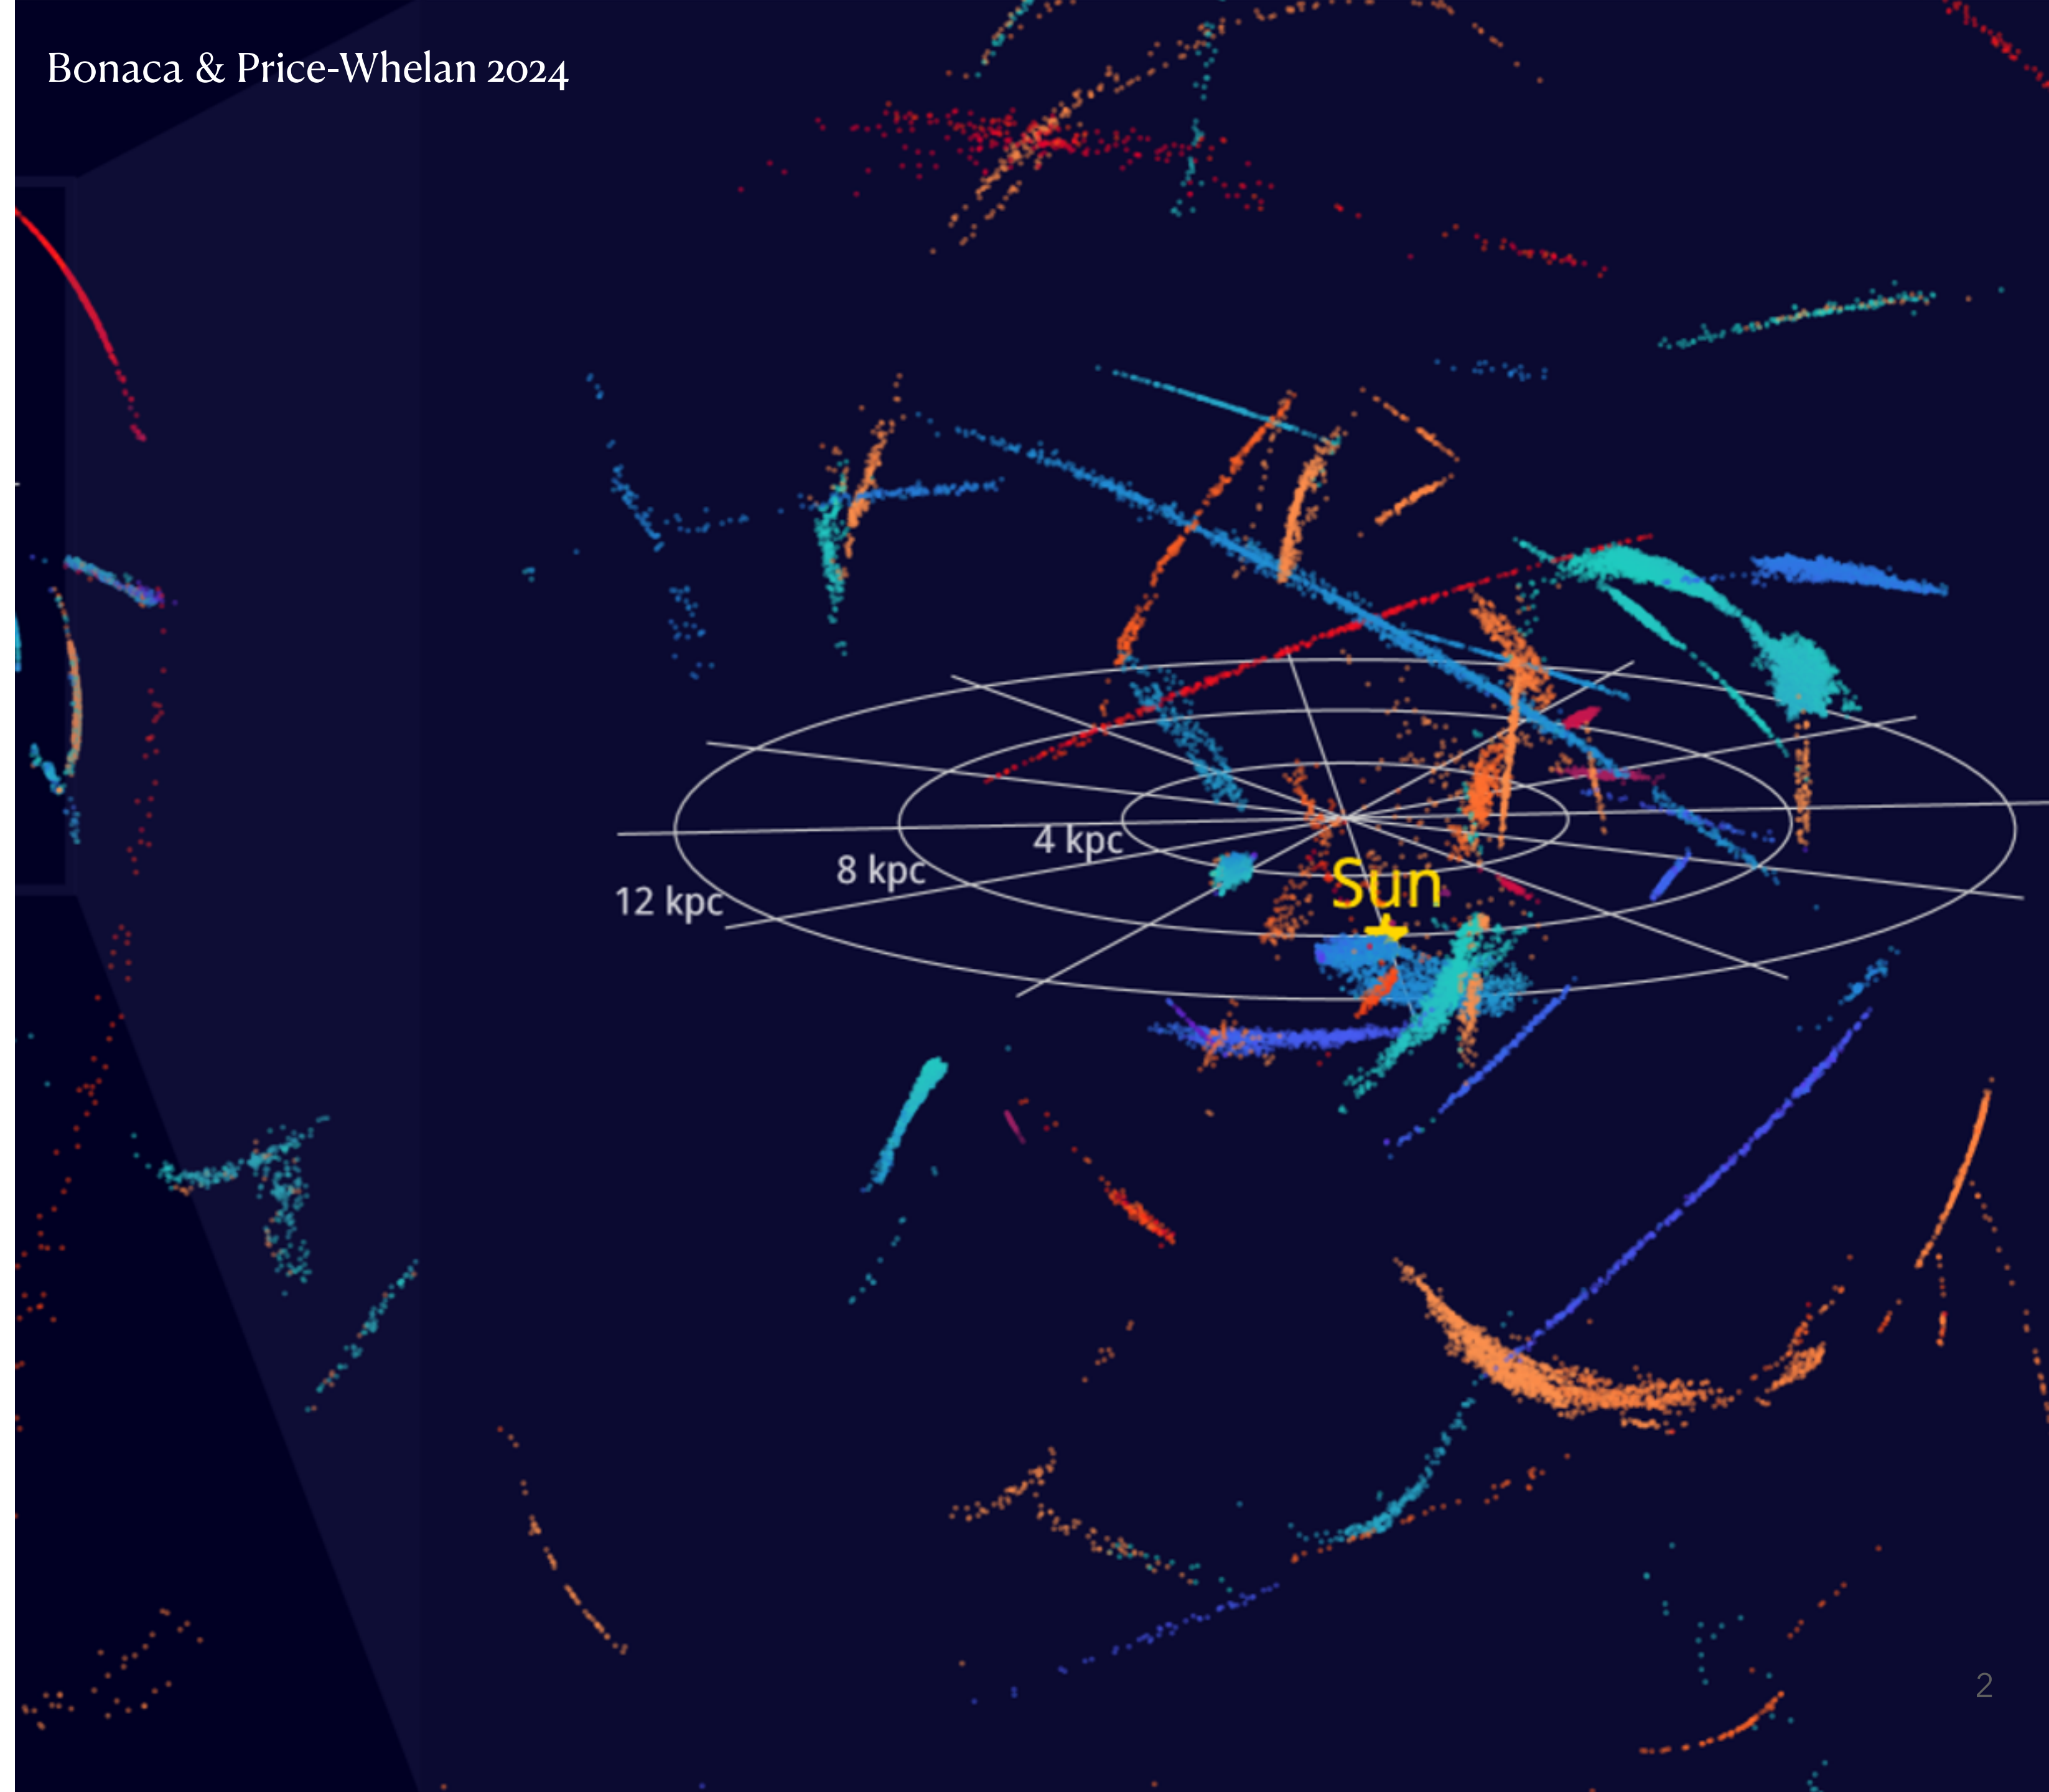

RICAP 2024

September 26, 2024

Stellar Streams in a nutshell

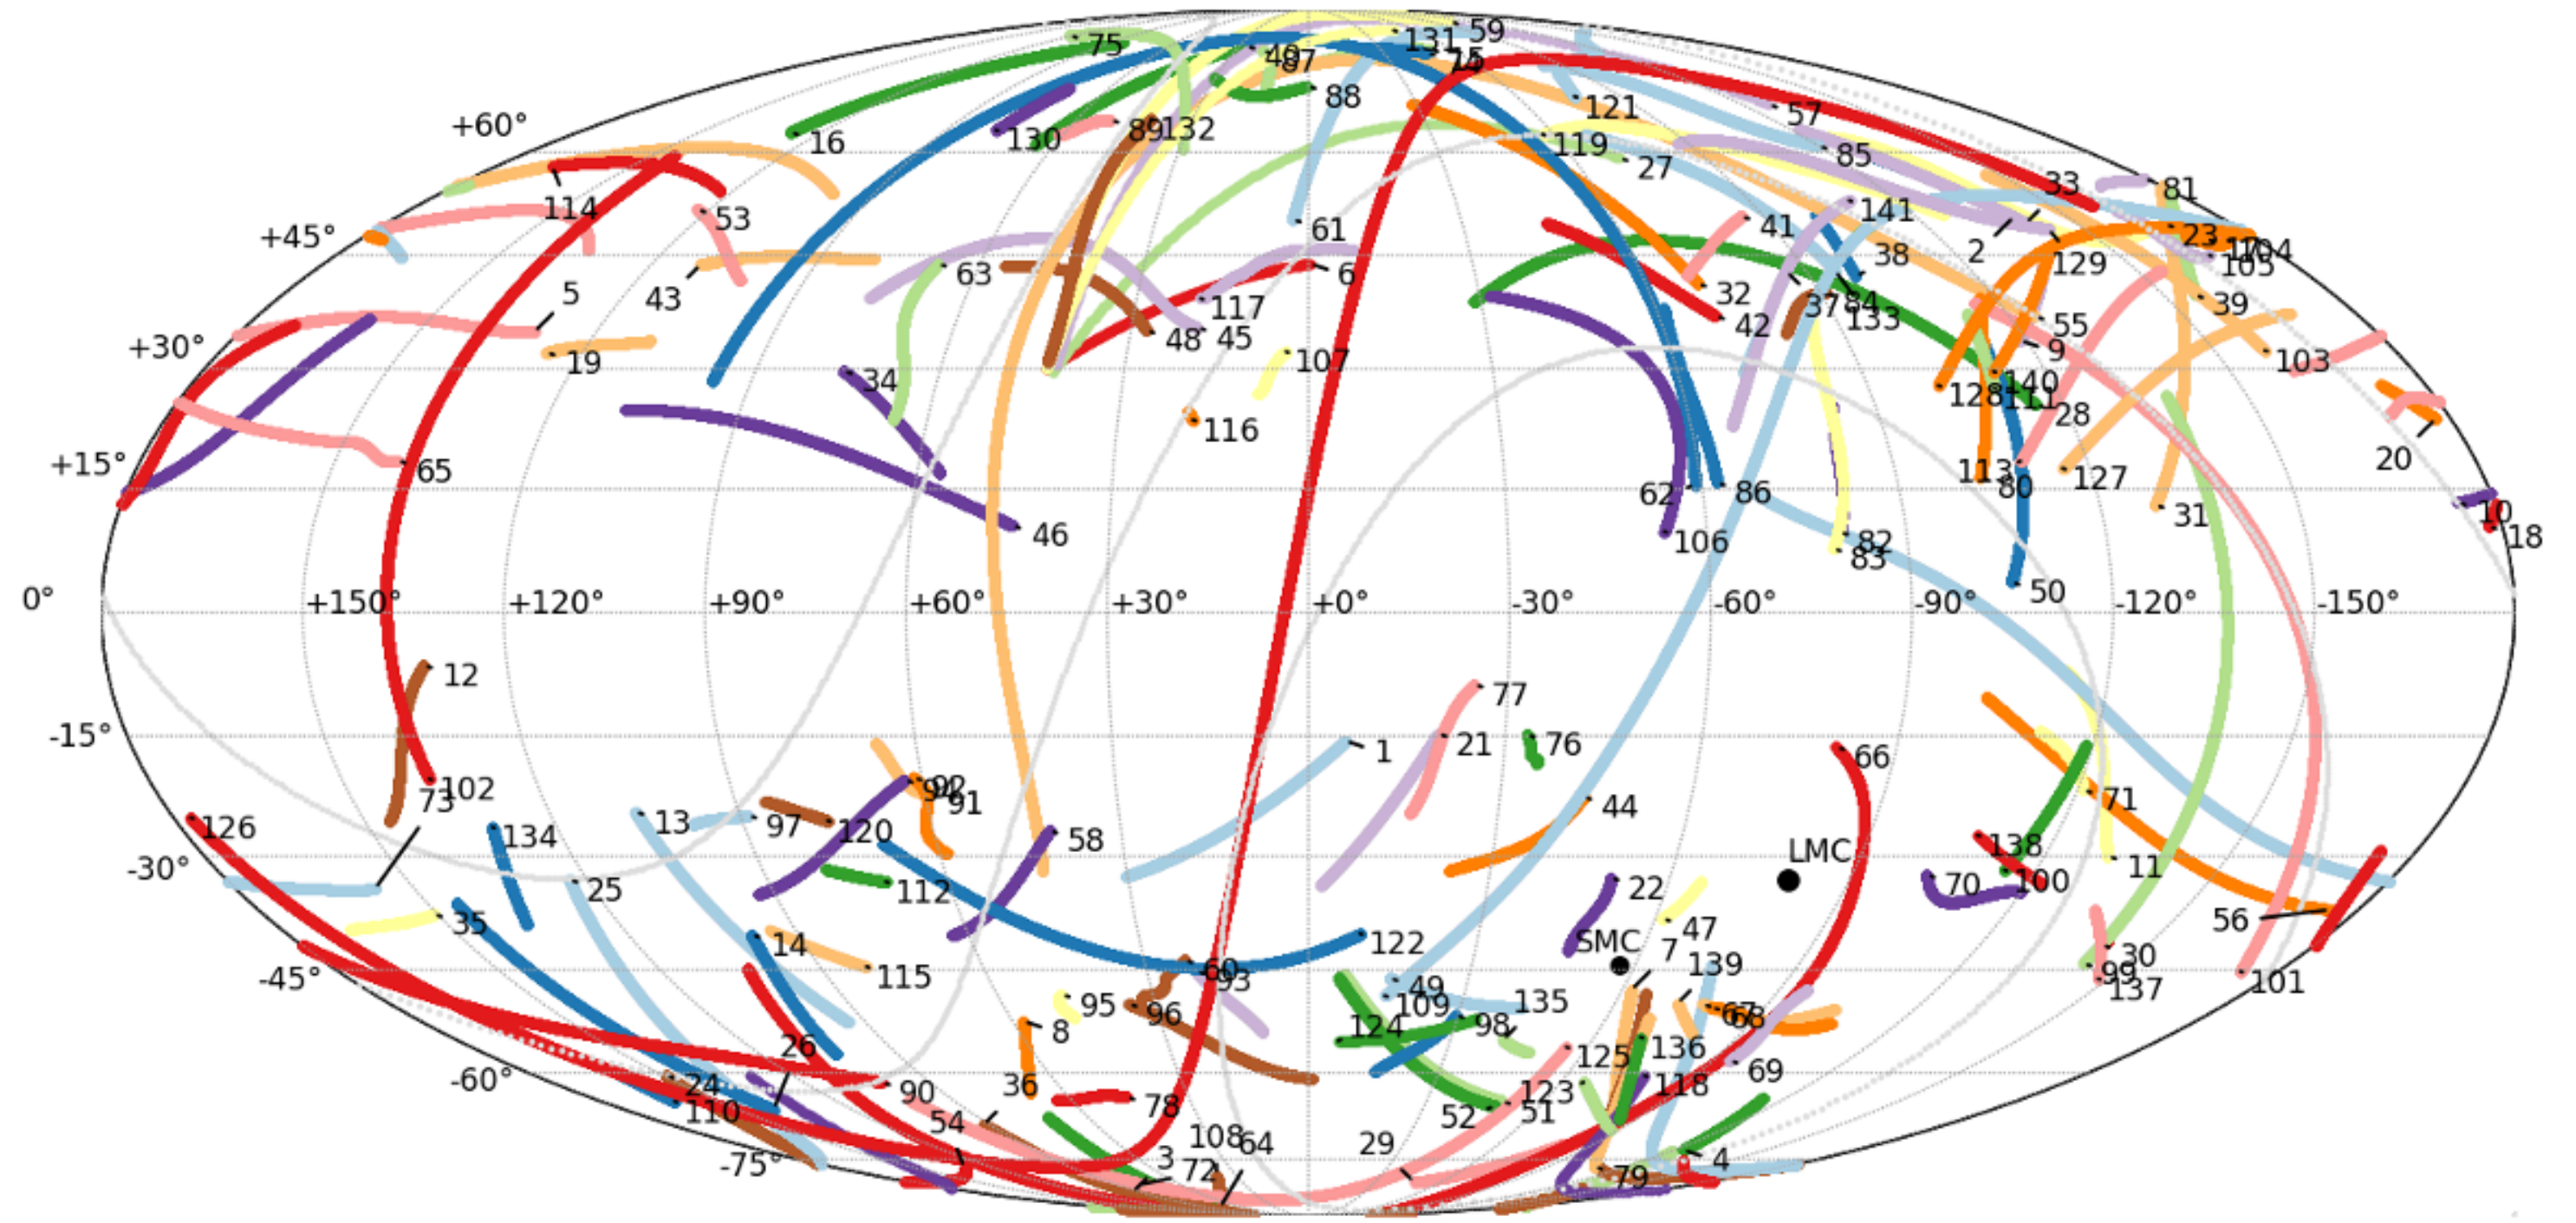

- * Remnants of satellites, globular clusters (GCs) or dwarf galaxies (dGs), heavily stripped in the tidal field of the host galaxy.
- * Extended structures, with lengths from 1 kpc to more than 100 kpc.
- * Range in heliocentric distance from a few kpc to 100 kpc.

Stellar Streams in a nutshell

* Observed by wide and deep sky surveys, such as SDSS, Pan-STARRS, Gaia and DESI.

* Around 100 stellar streams have been observed around the Milky Way (MW).

Sample Selection for dark matter searches

Criteria to build the best sample of stellar streams for gamma-ray dark matter (DM) searches, according to the most relevant properties:

*** Progenitor:**

Streams whose progenitor is a dG.

*** Distance:**

Streams closest to us ($\lesssim 100$ kpc).

*** Mass:**

Streams whose stellar mass is known.

Stream	(l, b) (°)	d_{Sun} (kpc)	Length (°)
Golden sample			
Indus	(332.26, -49.19)	16.6	18.2
LMS-1	(43.27, 55.46)	18.1	179.2
Orphan-Chenab	(264.90, 43.60)	20.0	230.6
PS1-D	(230.95, 32.67)	22.9	44.9
Turransburra	(219.72, -40.79)	27.5	13.7
Cetus-Palca	(147.90, -67.80)	33.4	100.9
Styx	(35.40, 75.40)	46.5	60.4
Elqui	(293.88, -77.20)	50.1	10.9
Silver sample			
Monoceros	(180.0, 25.0)	10.6	46.9
AntiCenter	(140.0, 35.0)	11.7	57.7
Sagittarius	(6.01, -14.89)	25.0	280.0
Other streams whose progenitor is a dG			
Jhelum-a	-	13.0	30.0
Jhelum-b	-	13.0	30.0
Parallel	(263.88, 61.26)	14.3	37.7
C-19	(102.29, -38.54)	18.0	29.7

'Golden' Sample

Fermi-LAT Data Analysis

* We search for any gamma-ray signal in Fermi-LAT data from the direction of the streams' cores.

'Golden' Sample

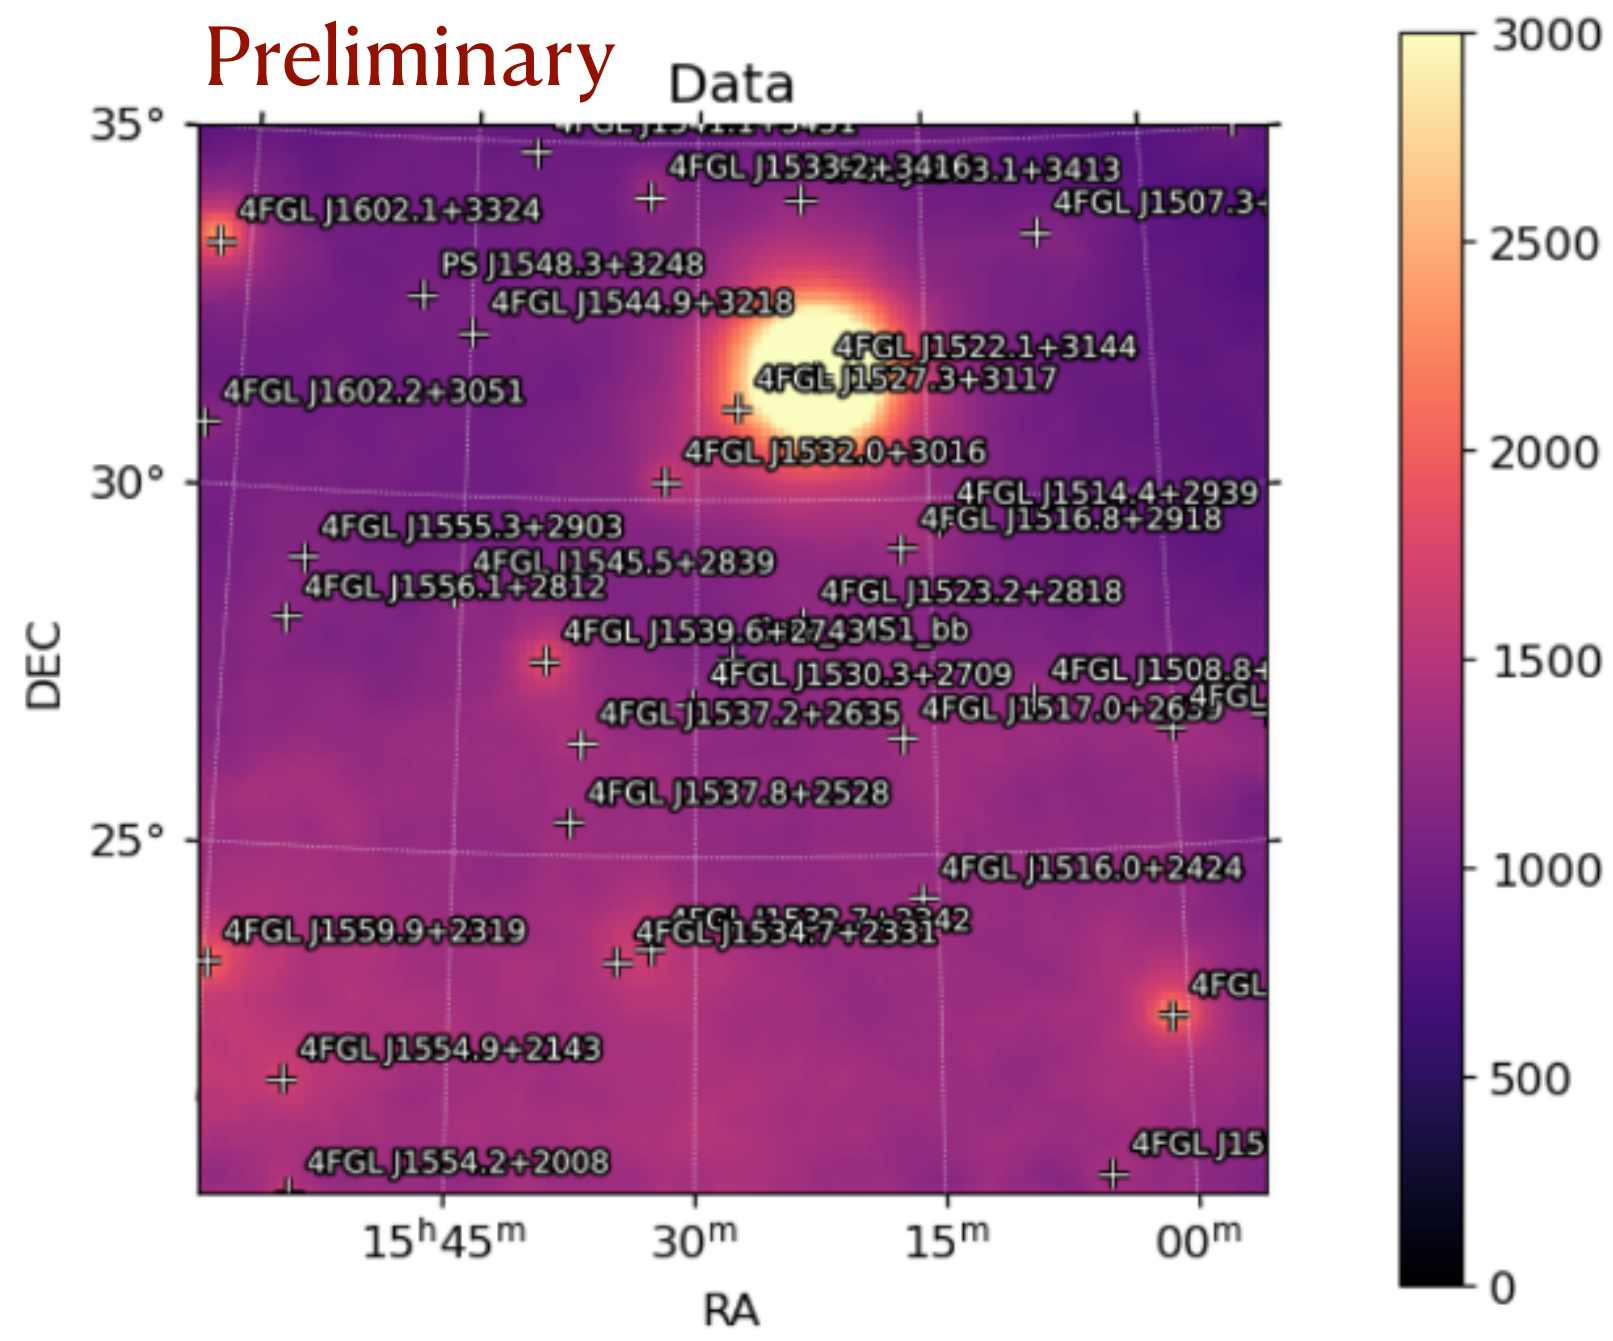

Spectral analysis technical setup

Time domain (Gregorian)	2008-08-04 to 2023-04-01
Time domain (MET)	239557417 to 702032312
Energy range	500 MeV - 500 GeV
IRF	P8R3_SOURCE_V3
Event type	FRONT + BACK
Point-source catalog	4FGL-DR4
ROI size	15° x 15°
Angular bin size	0.01°
Bins per energy decade	8
Galactic diffuse model	gll_iem_v07.fits
Isotropic diffuse model	iso_P8R3_SOURCE_V3_v1.txt

- * We perform the data analysis with the Fermipy python package.
- * Sources within 3 degrees from stream's core: free normalization and spectral shape.
- * Galactic diffuse component: free normalization and spectral index.
- * Isotropic diffuse component: free normalization.

LAT Analysis Results: Example of skymaps

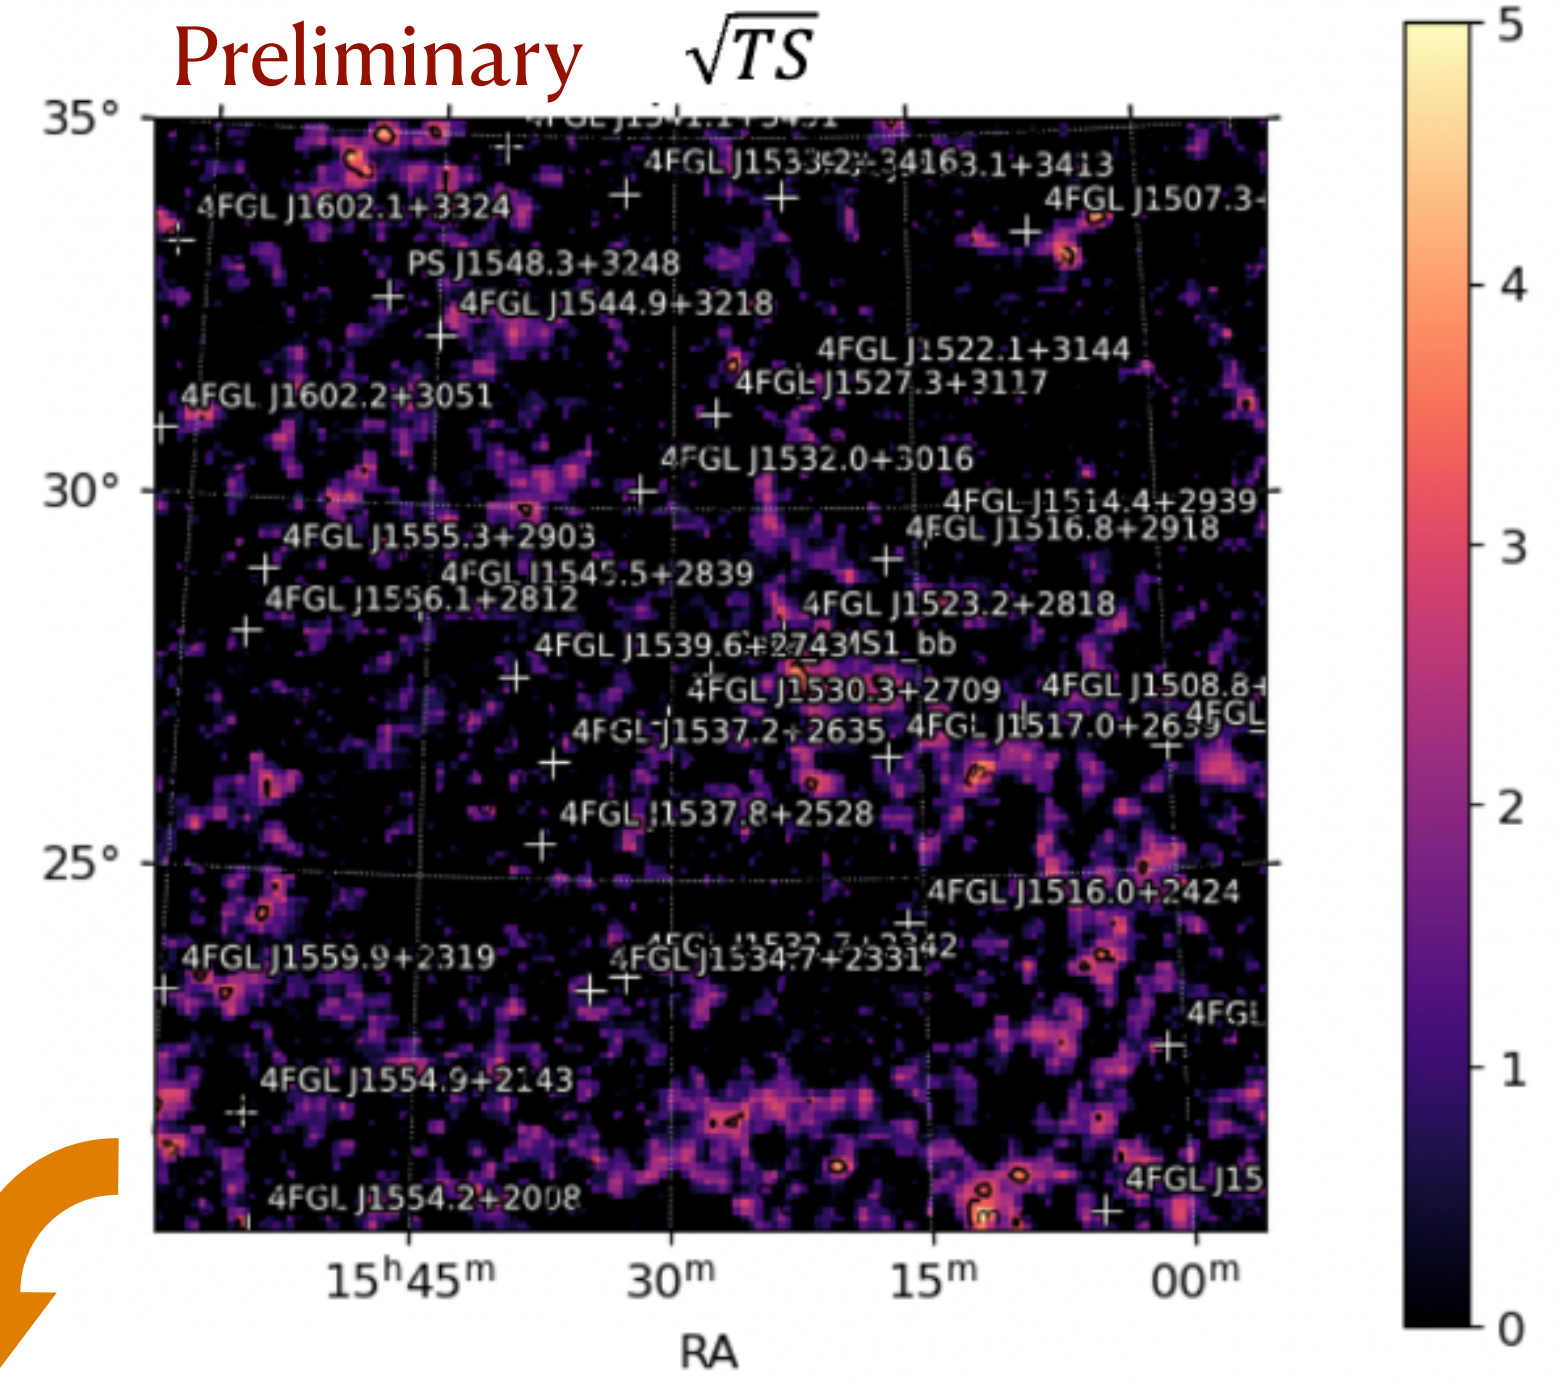

LMS-1 ROI – Data map

LMS-1 ROI – Model map

LMS-1 ROI – TS map

Test statistic (TS): positive deviations with respect to the model

$$TS = -2 \log \left(\frac{\mathcal{L}(H_1)}{\mathcal{L}(H_0)} \right)$$

← Likelihood of the alternative (existing DM source) hypothesis
← Likelihood under the null (no source) hypothesis

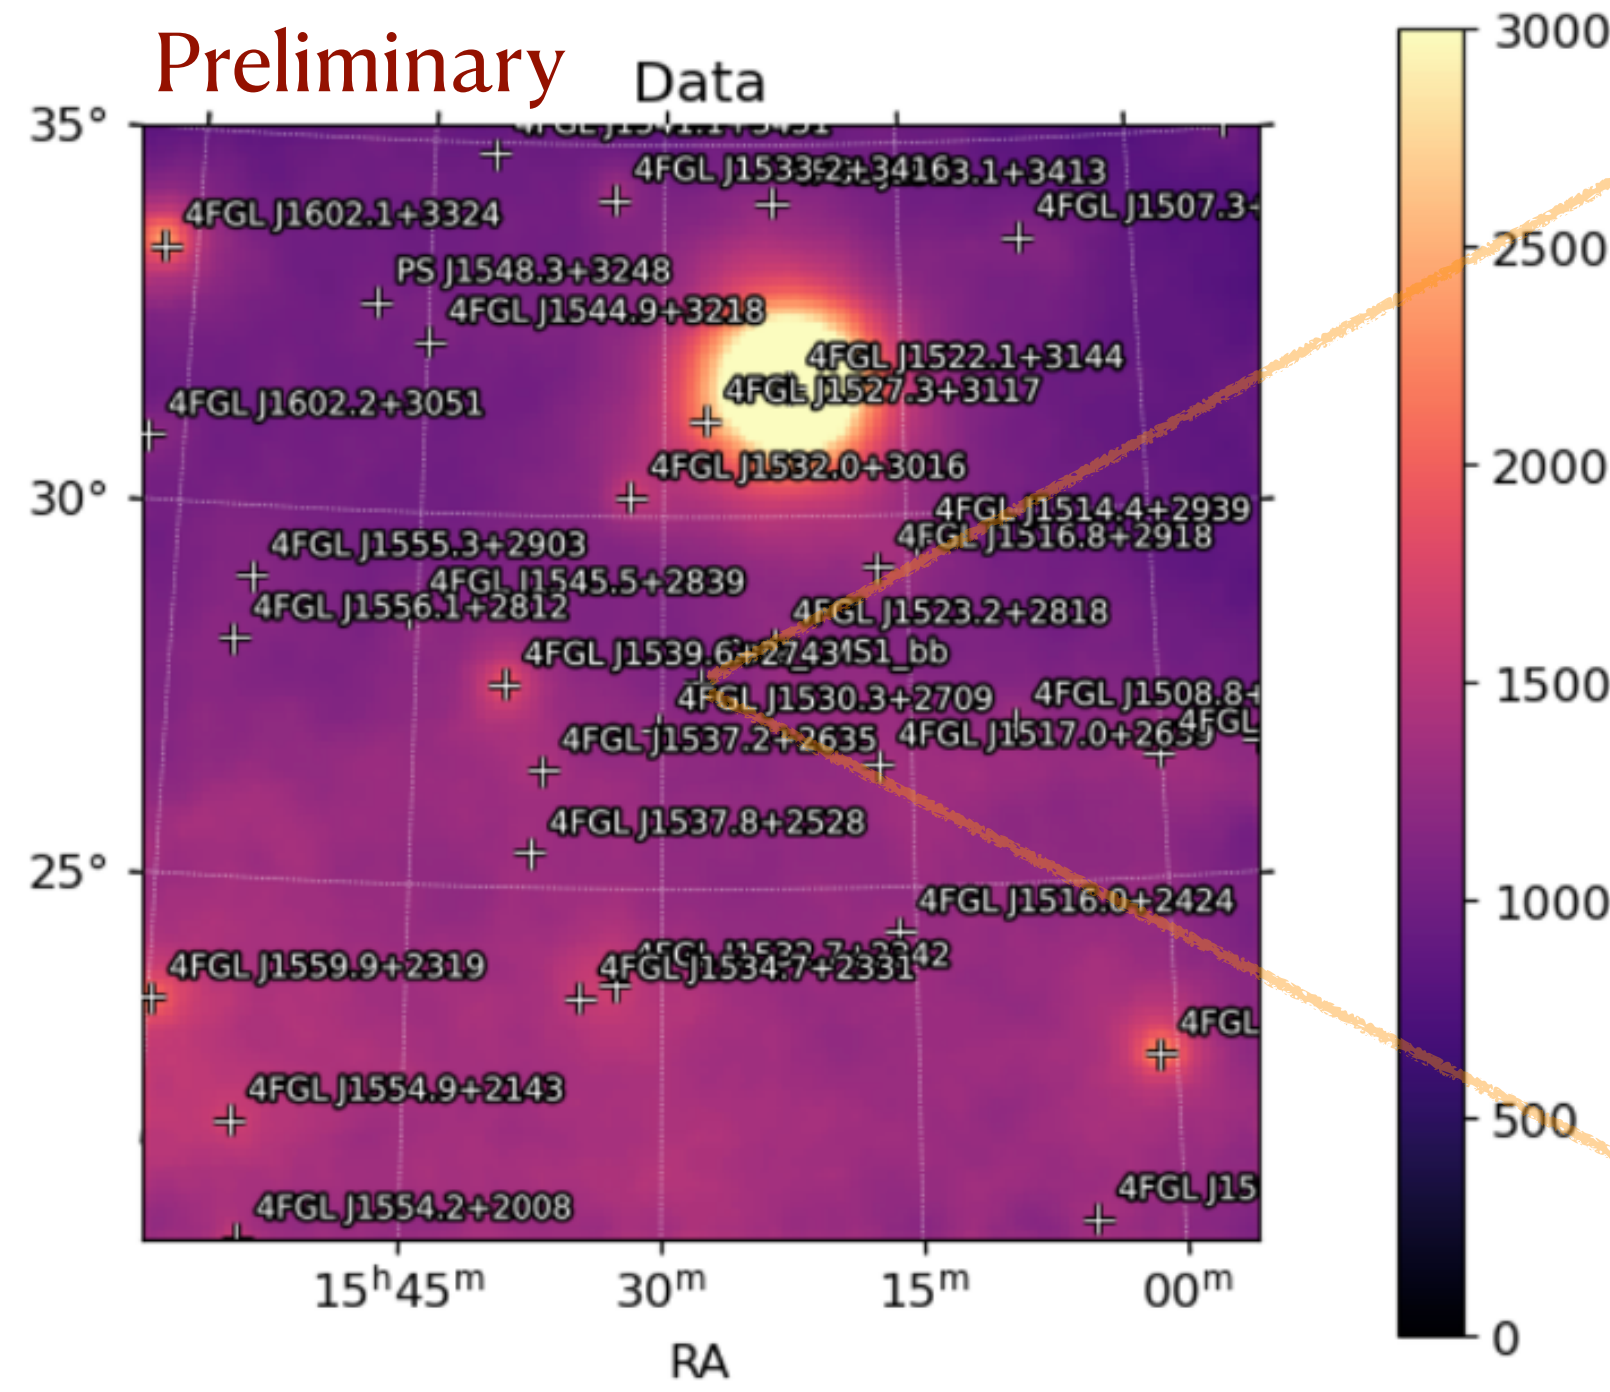

$TS \sim \sigma^2$

Analysis Results: Flux upper limits

No significant emission is detected from any of the streams in our sample.

We introduce a putative DM source annihilating at the center of every ROI

Flux upper limits 95 % confidence level (C.L.)

Example for LMS-1 stream

DM Constraints

- * In the absence of a signal, we put constraints on the DM particle properties.
- * Assuming that all the DM is in the form of Weakly Interacting Massive Particles (WIMPs), the expected flux due to WIMPs annihilation ([Bergström et al. 1998](#)):

$$F(E, \Delta\Omega, l.o.s) = \frac{d\phi_\gamma}{dE}(E) \times J(\Delta\Omega, l.o.s)$$

Particle physics term
(DM particle mass, annihilation cross-section $\langle\sigma v\rangle$, and DM spectrum)

Astrophysical J-factor

$$J(\Delta\Omega, l.o.s) \propto \iint \rho_{DM}^2 dl d\Omega$$

DM density profile

DM Constraints

DM Constraints

$$J(\Delta\Omega, l.o.s) \propto \iint \rho_{DM}^2 dl d\Omega$$

DM Modelling

- * We assume that the streams maintain the same density distribution as their progenitors within the core ($r \leq r_s$) (e.g., [Aguirre-Santaella et al. 2024](#)).
- * Rest of the DM outside r_s gets lost due to tidal stripping.
- * We model the streams' core with a truncated Navarro-Frenk-White (NFWt) DM density profile.

If

$$\left\{ \begin{array}{l} r \leq r_s \longrightarrow \rho_{NFWt}(r) = \frac{\rho_0}{\left(\frac{r}{r_s}\right) \left(1 + \frac{r}{r_s}\right)^2} \\ r > r_s \longrightarrow \rho_{NFWt}(r) = 0 \end{array} \right.$$

ρ_0 : characteristic DM density

r_s : scale radius

ρ_0 and r_s are obtained starting from the initial DM mass (M_{200}) and assuming the [Moliné et al. 2017](#) subhalo concentration-mass relation.

DM Modelling

- * We assume that the streams maintain the same density distribution as their progenitors within the core ($r \leq r_s$) (e.g., [Aguirre-Santaella et al. 2024](#)).
- * Rest of the DM outside r_s gets lost due to tidal stripping.
- * We model the streams' core with a truncated Navarro-Frenk-White (NFWt) DM density profile.

$$r \leq r_s \longrightarrow \rho_{NFWt}(r) = \frac{\rho_0}{\left(\frac{r}{r_s}\right) \left(1 + \frac{r}{r_s}\right)^2}$$

ρ_0 and r_s are obtained starting from the initial DM mass (M_{200}) and assuming the [Moliné et al. 2017](#) subhalo concentration-mass relation.

- * The extension in the sky of each stream's core will be given by the angle subtended by r_s :

$$\theta_s = \arctan\left(\frac{r_s}{d_{Sun}}\right)$$

DM Modelling

* Starting from the known stellar mass, we adopt three different mass-to-light (M/L) ratios to estimate the ‘original’ DM mass of each stream at accretion time, M_{200} .

Stream	$\frac{M_{200}}{10^4} (M_{\odot})$		
	<i>Low</i>	<i>Bench.</i>	<i>High</i>
Indus	3.40	17.00	170.00
LMS-1	10.00	50.00	500.00
Orphan-Chenab	16.00	80.00	800.00
PS1-D	0.75	3.75	37.50
Turramburra	0.76	3.80	38.00
Cetus-Palca	150.00	750.00	7500.00
Styx	1.80	9.00	90.00
Elqui	1.04	5.20	52.00

Low: M/L = 2
(same DM mass than baryonic mass)

Benchmark / Intermediate: M/L = 5

High: M/L = 50

Typical M/L for dGs: 10 – 1000

(e. g. [M. Mateo 1998](#),
[M. A. Sánchez-Conde et al. 2011](#),
[Q. Guo et al. 2019](#)).

DM Modelling

* Starting from the known stellar mass, we adopt three different mass-to-light (M/L) ratios to estimate the ‘original’ DM mass of each stream at accretion time, M_{200} .

Stream	$\frac{M_{200}}{10^4} (M_{\odot})$		
	<i>Low</i>	<i>Bench.</i>	<i>High</i>
Indus	3.40	17.00	170.00
LMS-1	10.00	50.00	500.00
Orphan-Chenab	16.00	80.00	800.00
PS1-D	0.75	3.75	37.50
Turrampurra	0.76	3.80	38.00
Cetus-Palca	150.00	750.00	7500.00
Styx	1.80	9.00	90.00
Elqui	1.04	5.20	52.00

Low: M/L = 2
(same DM mass than baryonic mass)

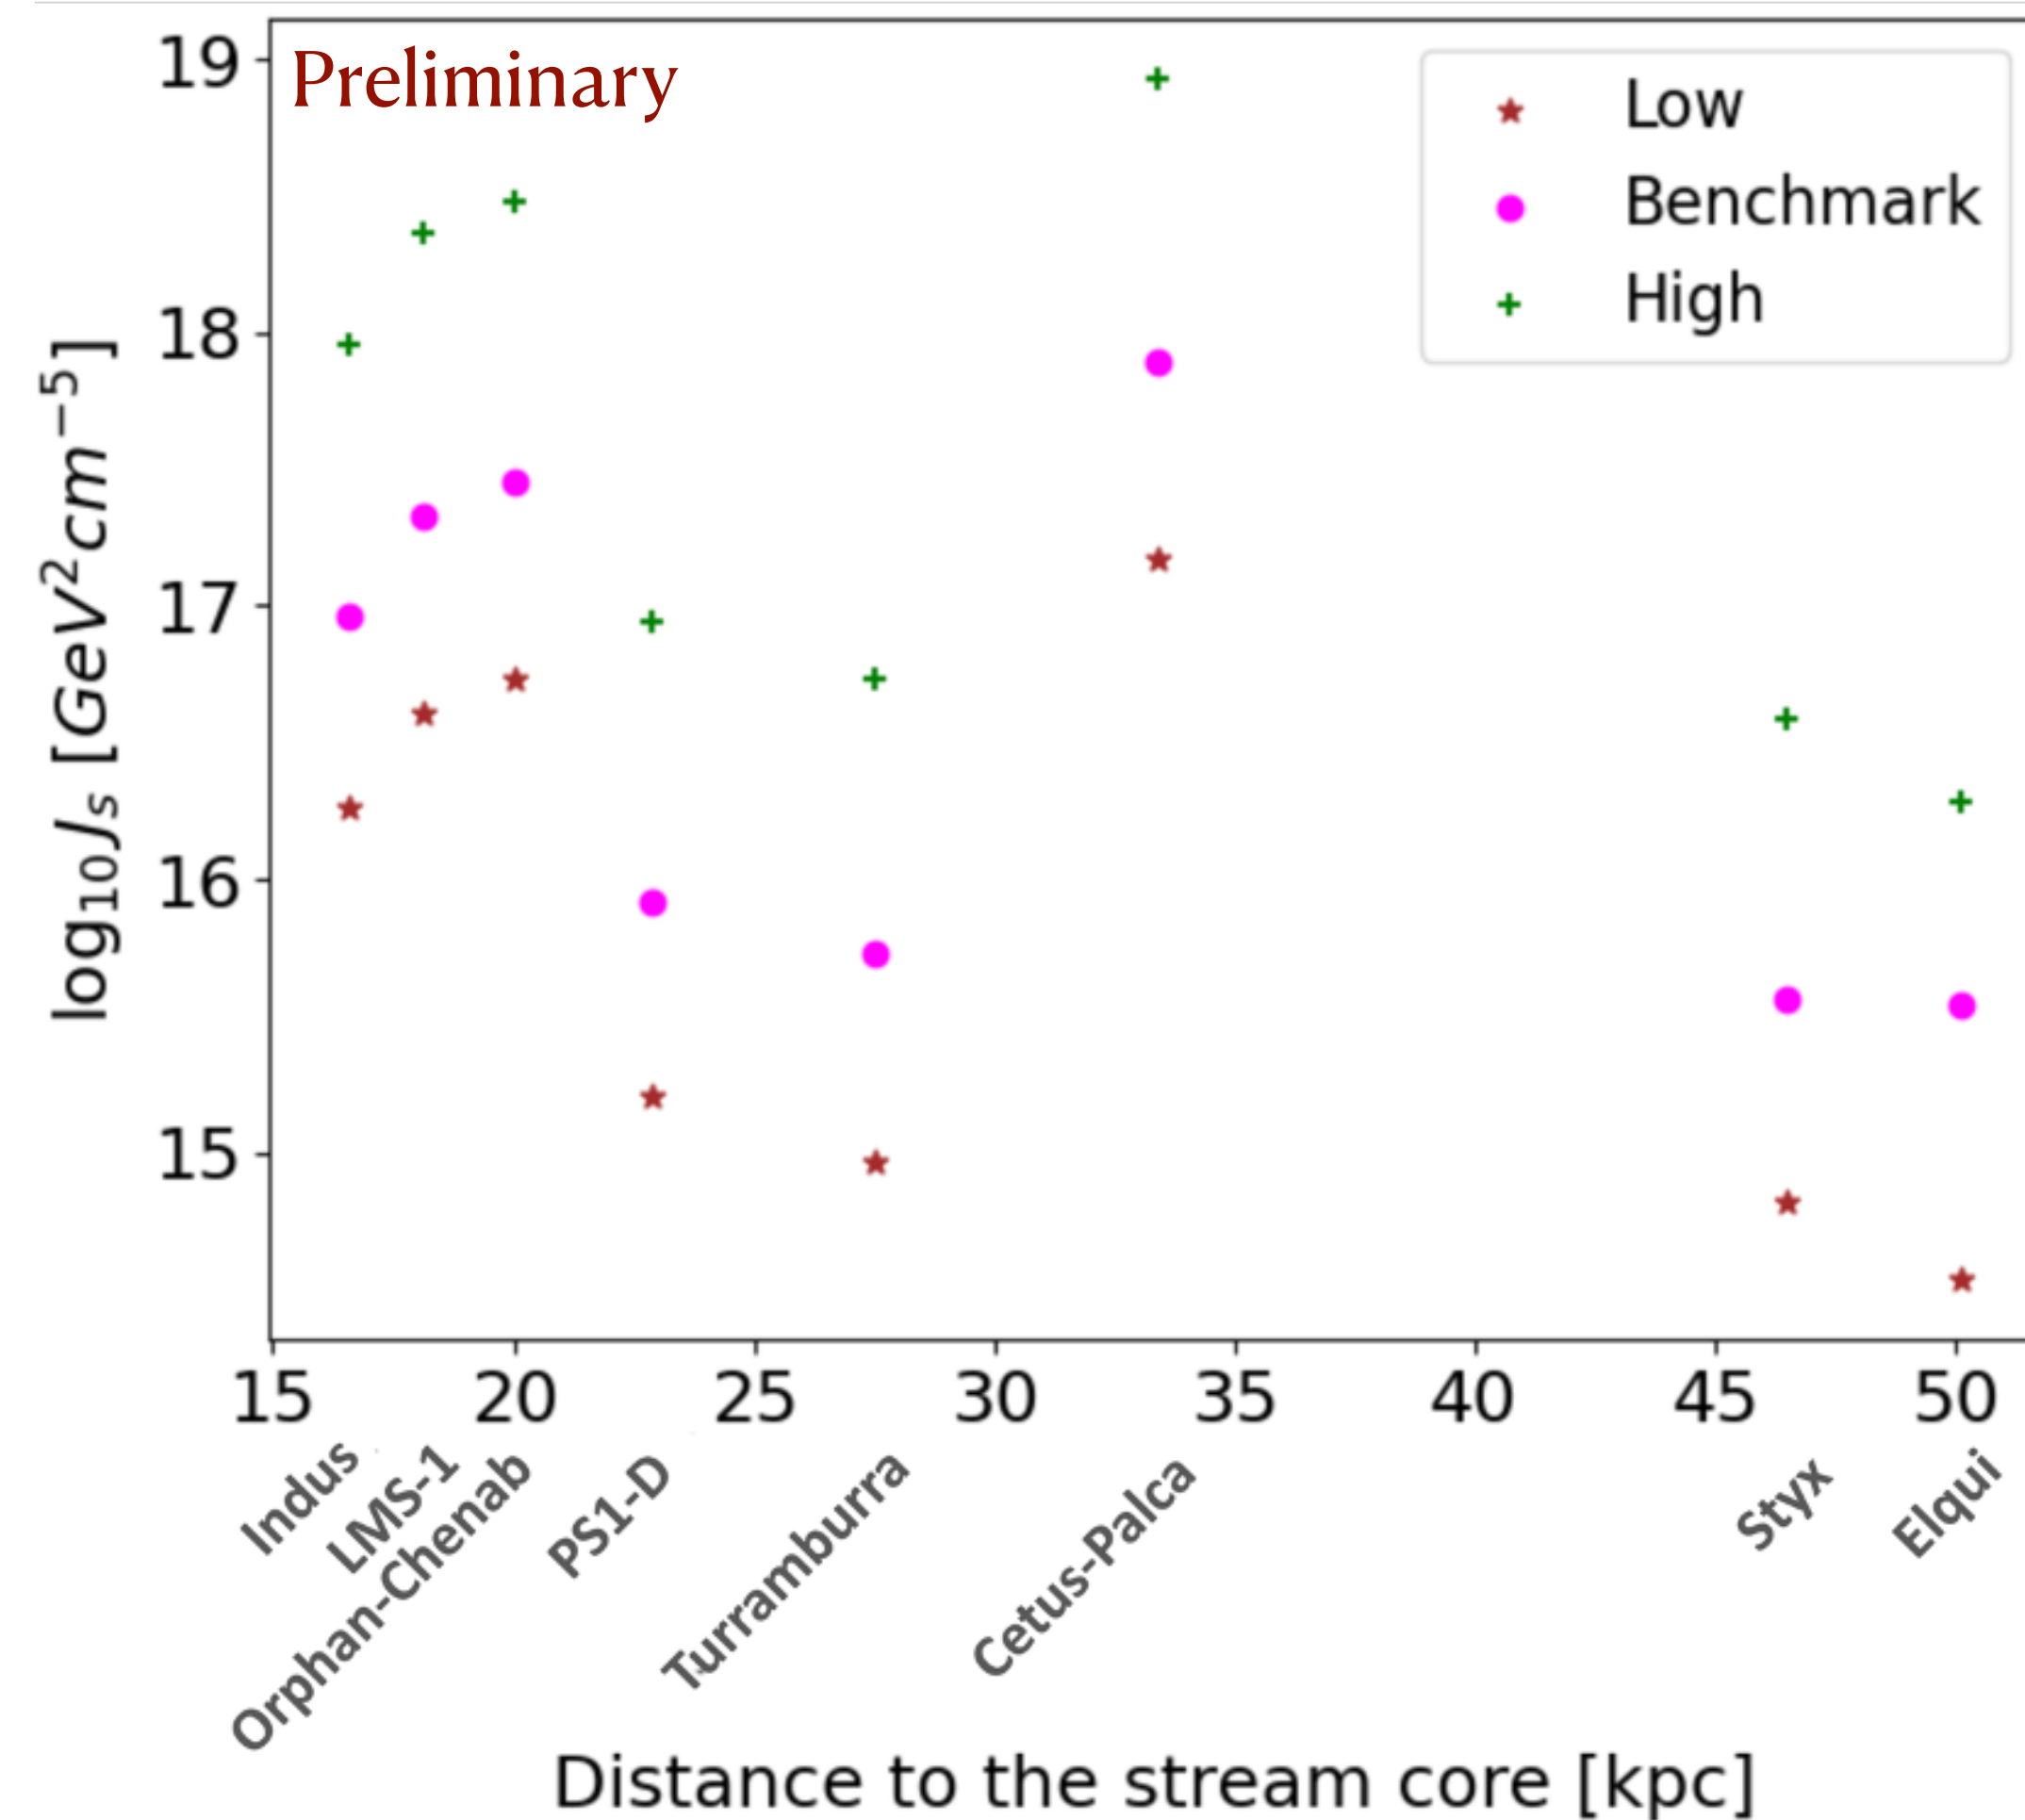

Benchmark / Intermediate: M/L = 5

High: M/L = 50

★ In cases where no estimates of the current streams’ mass is available, we consider the stellar mass of the progenitor as the stellar mass of the stream: during the stretching process, the streams lose DM while we assume that the total baryon matter content remains the same.

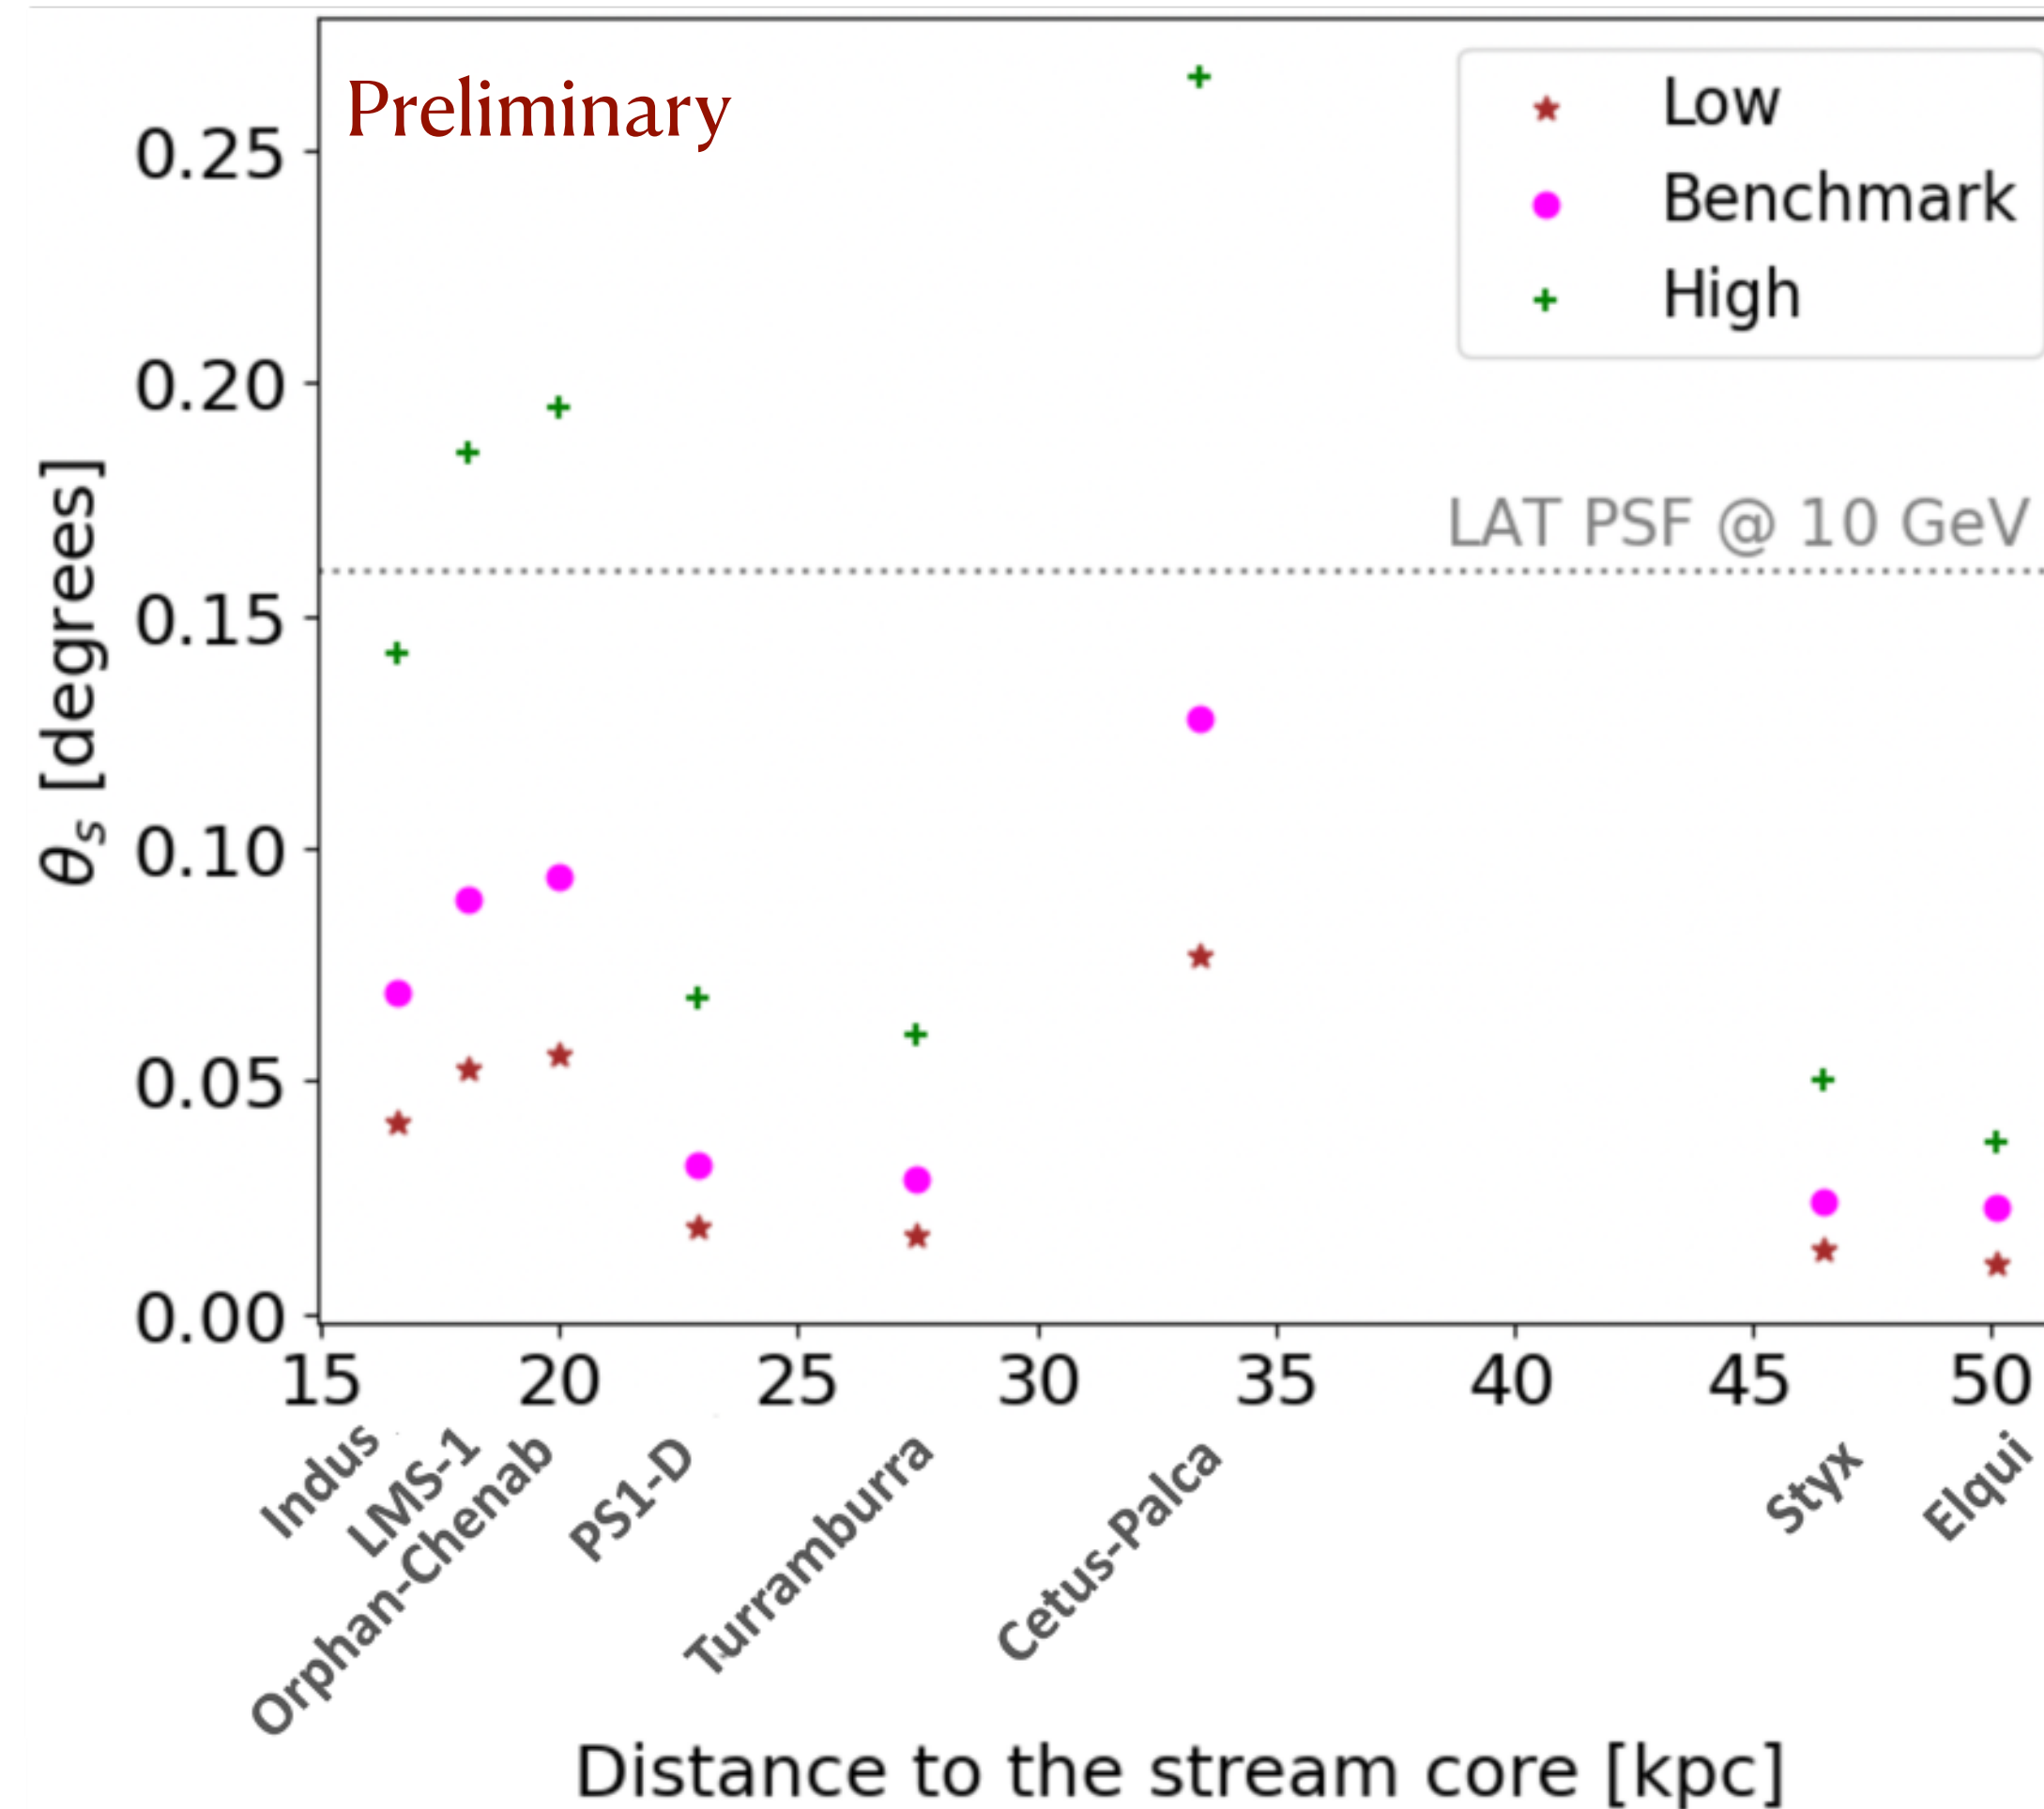

Streams' J-factors and Angular sizes

J_s : J-factor integrated up to the scale radius r_s

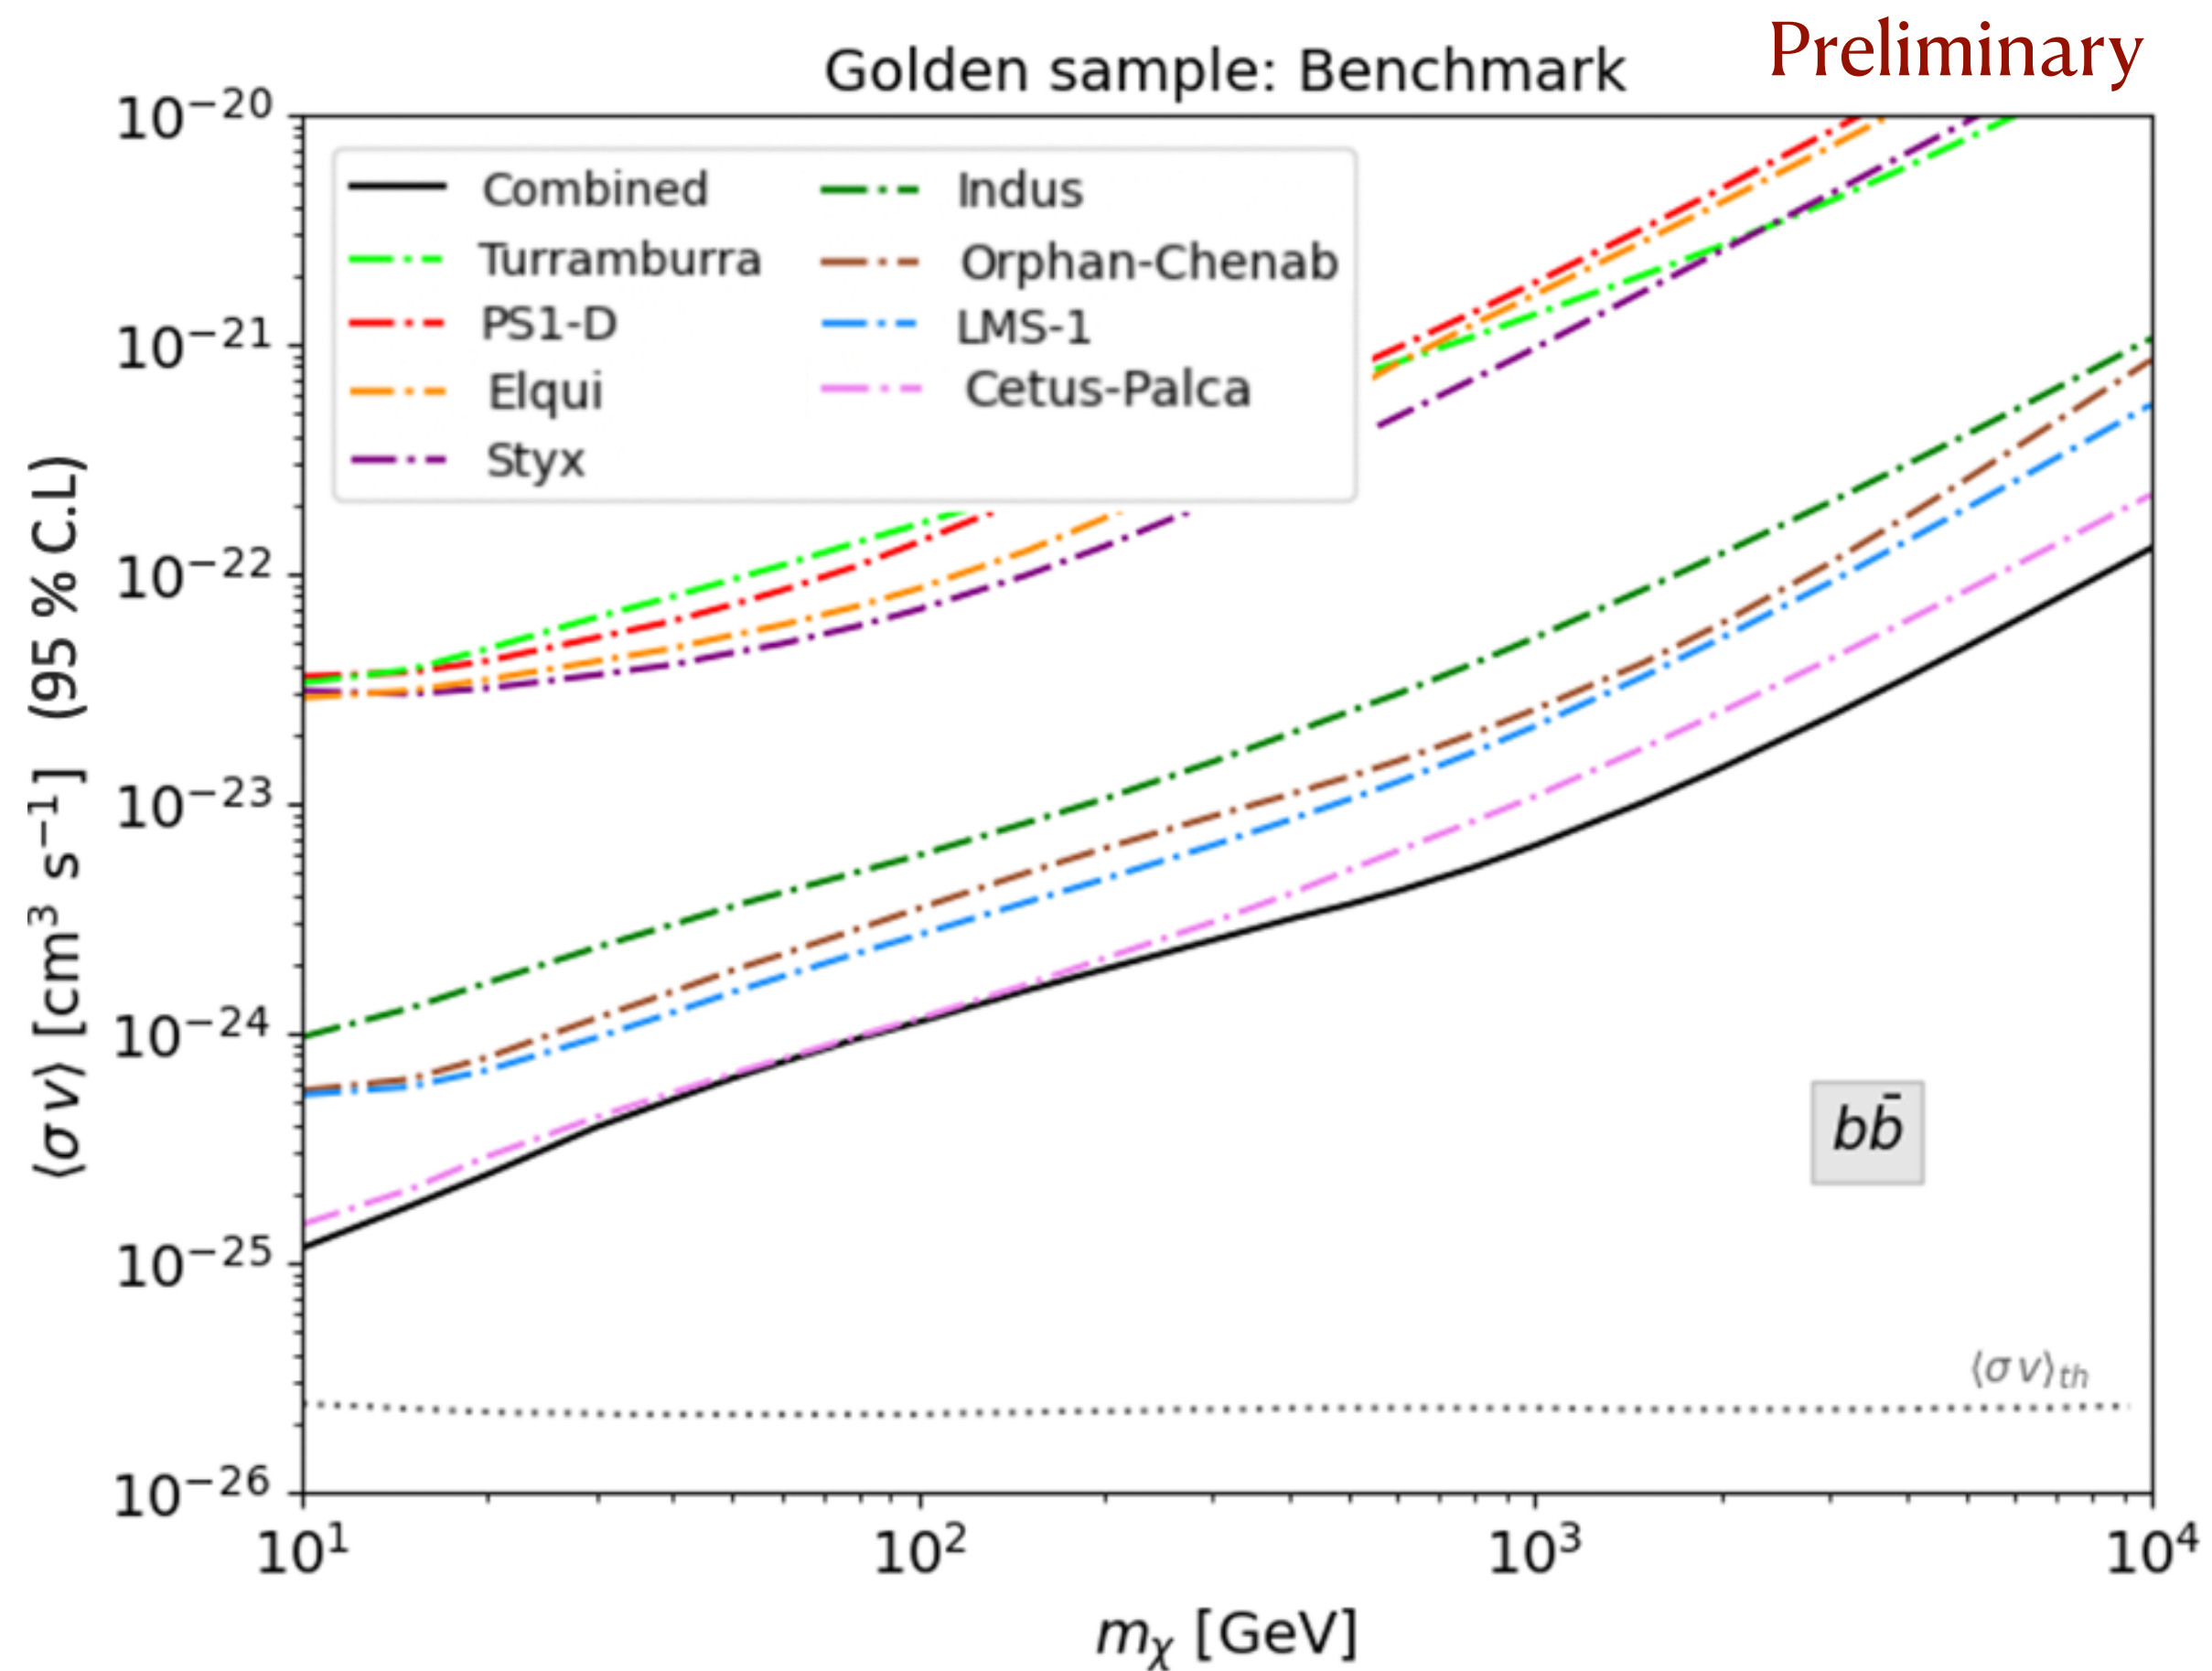

Streams' J-factors and Angular sizes

These objects are considered as point-like sources for the LAT

Angular resolution of the LAT at 10 GeV (1σ , 68% containment)

DM constraints: Golden Sample, Benchmark case

Combined Likelihood Analysis

- * Once the individual analysis of each stream is done, we combine the results obtained for each one by summing together the individual log-likelihood profiles independently for each energy bin, to obtain a global likelihood:

Combined likelihood for a particular DM annihilation channel as a function of the DM mass and $\langle\sigma v\rangle$ for all targets

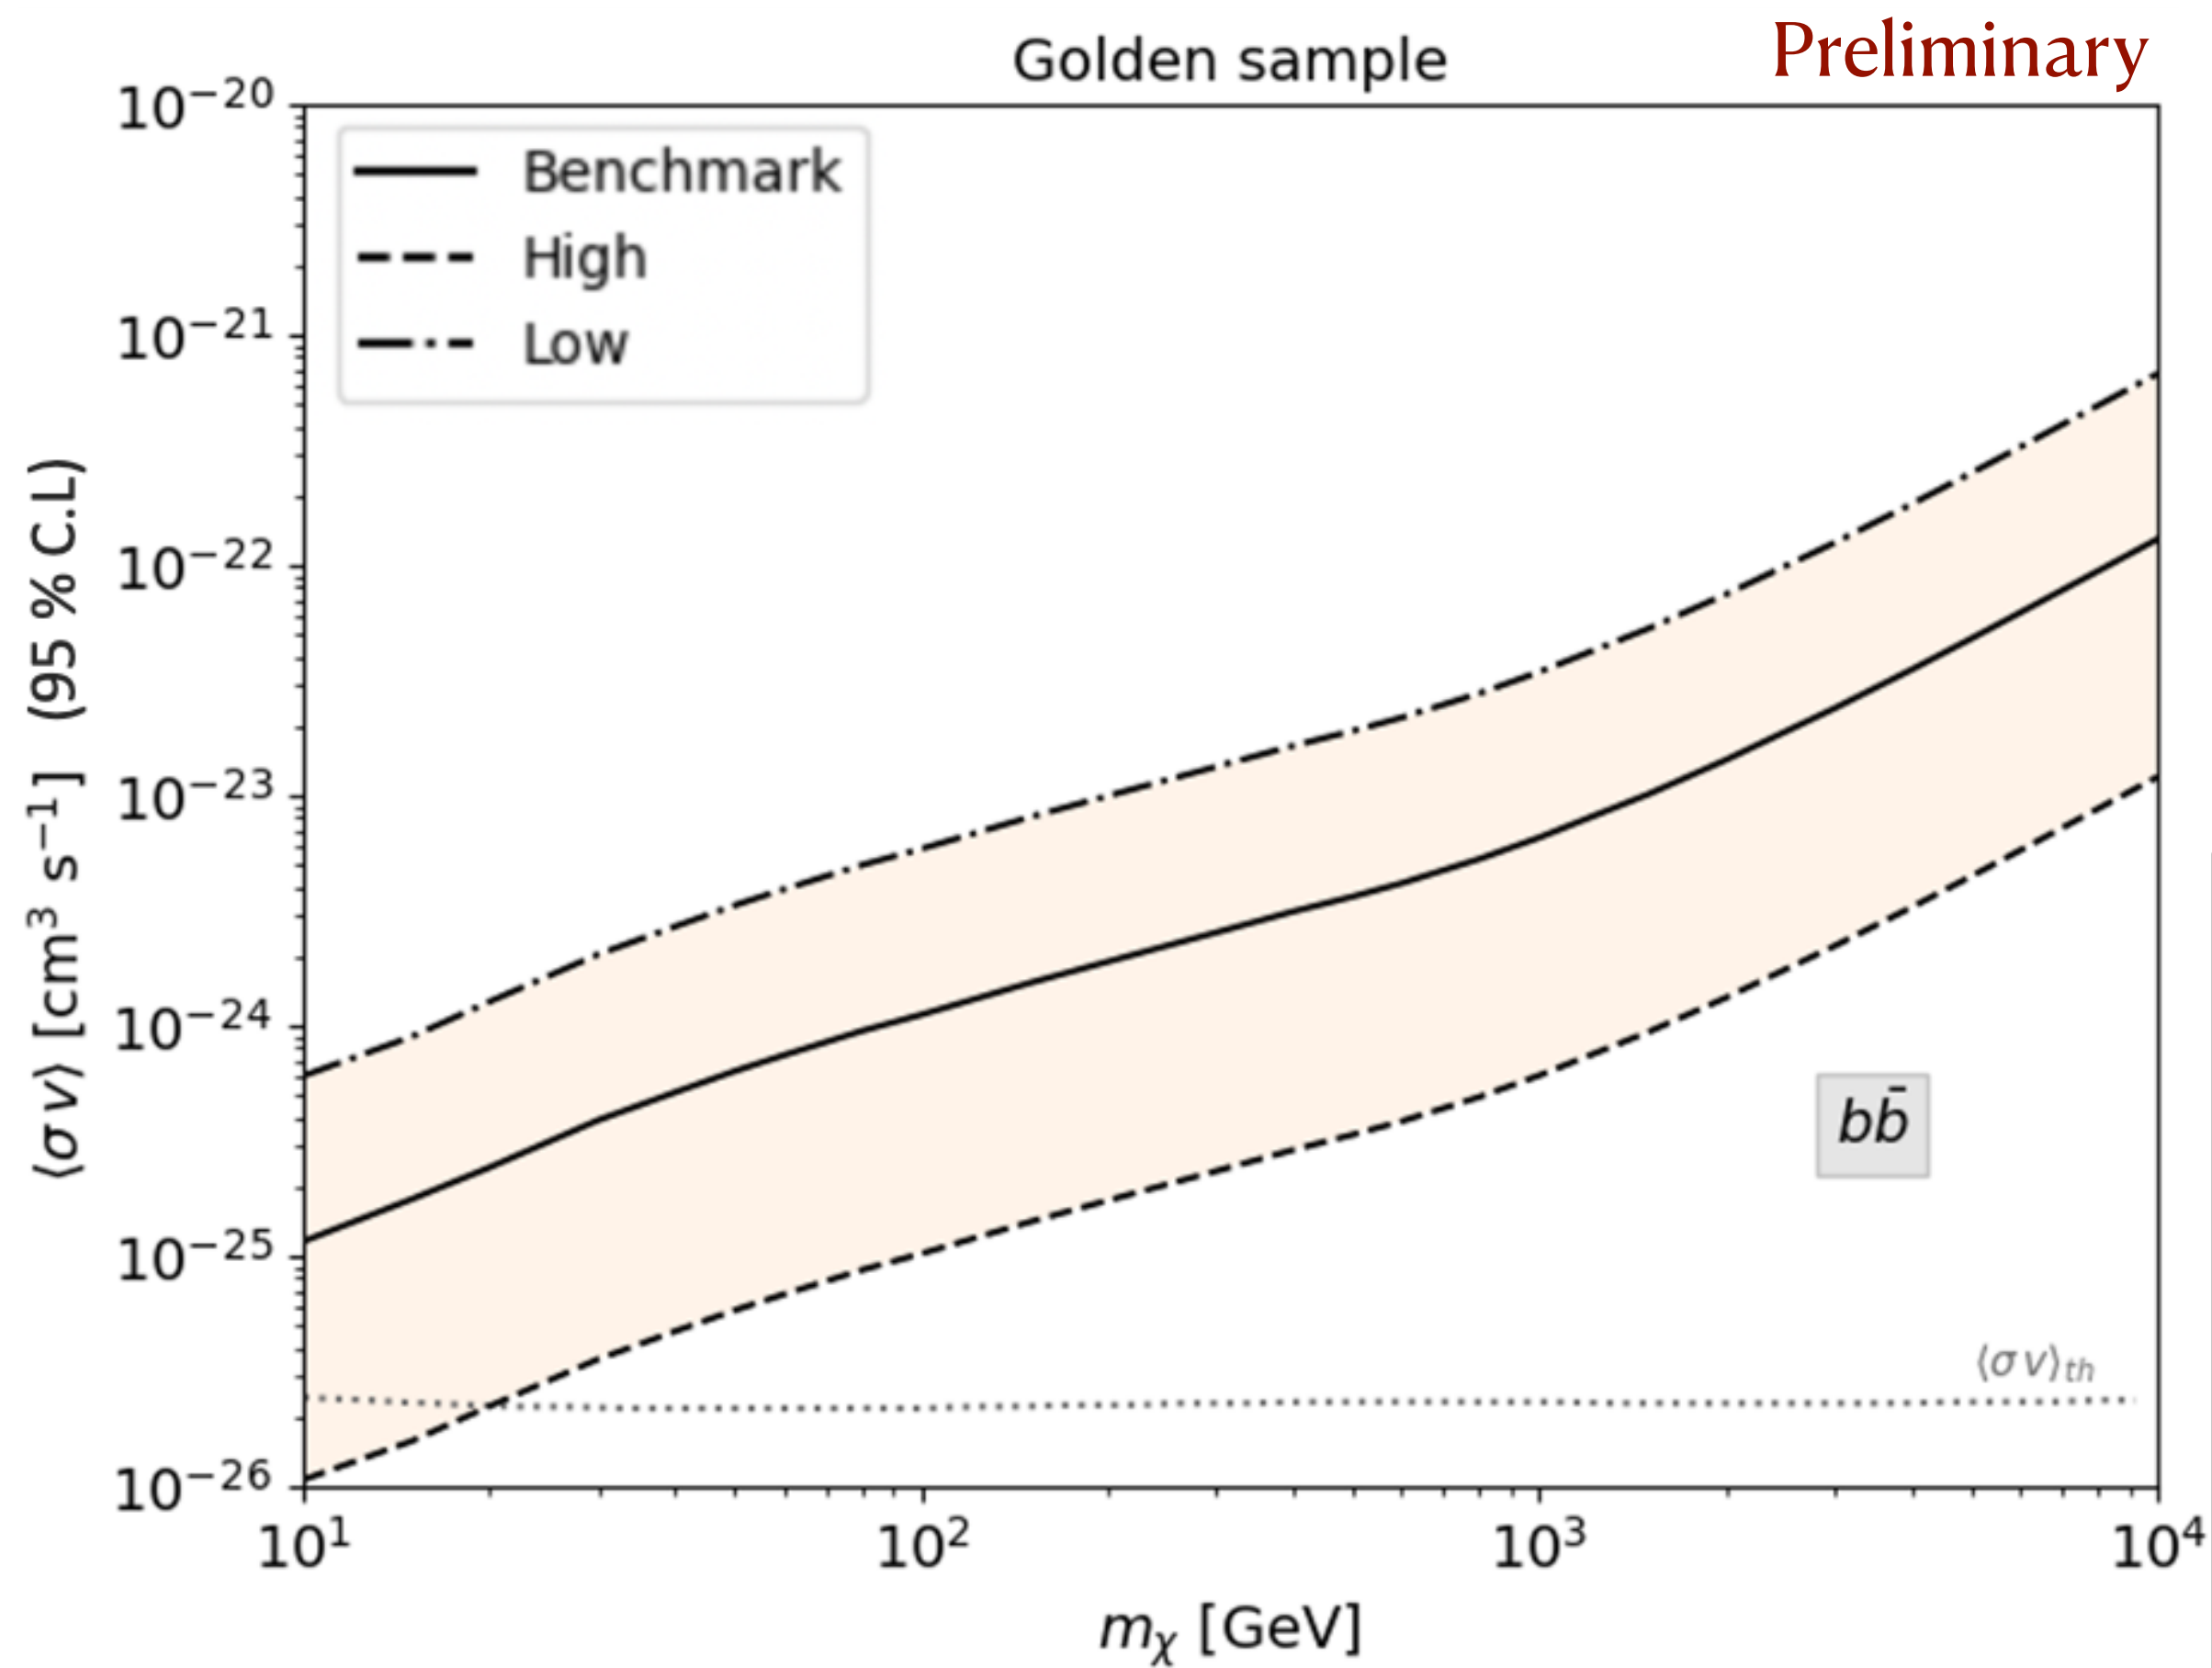

DM parameters
($\langle\sigma v\rangle$ and m_χ)

Parameters in the background model
(i.e., the nuisance parameters)

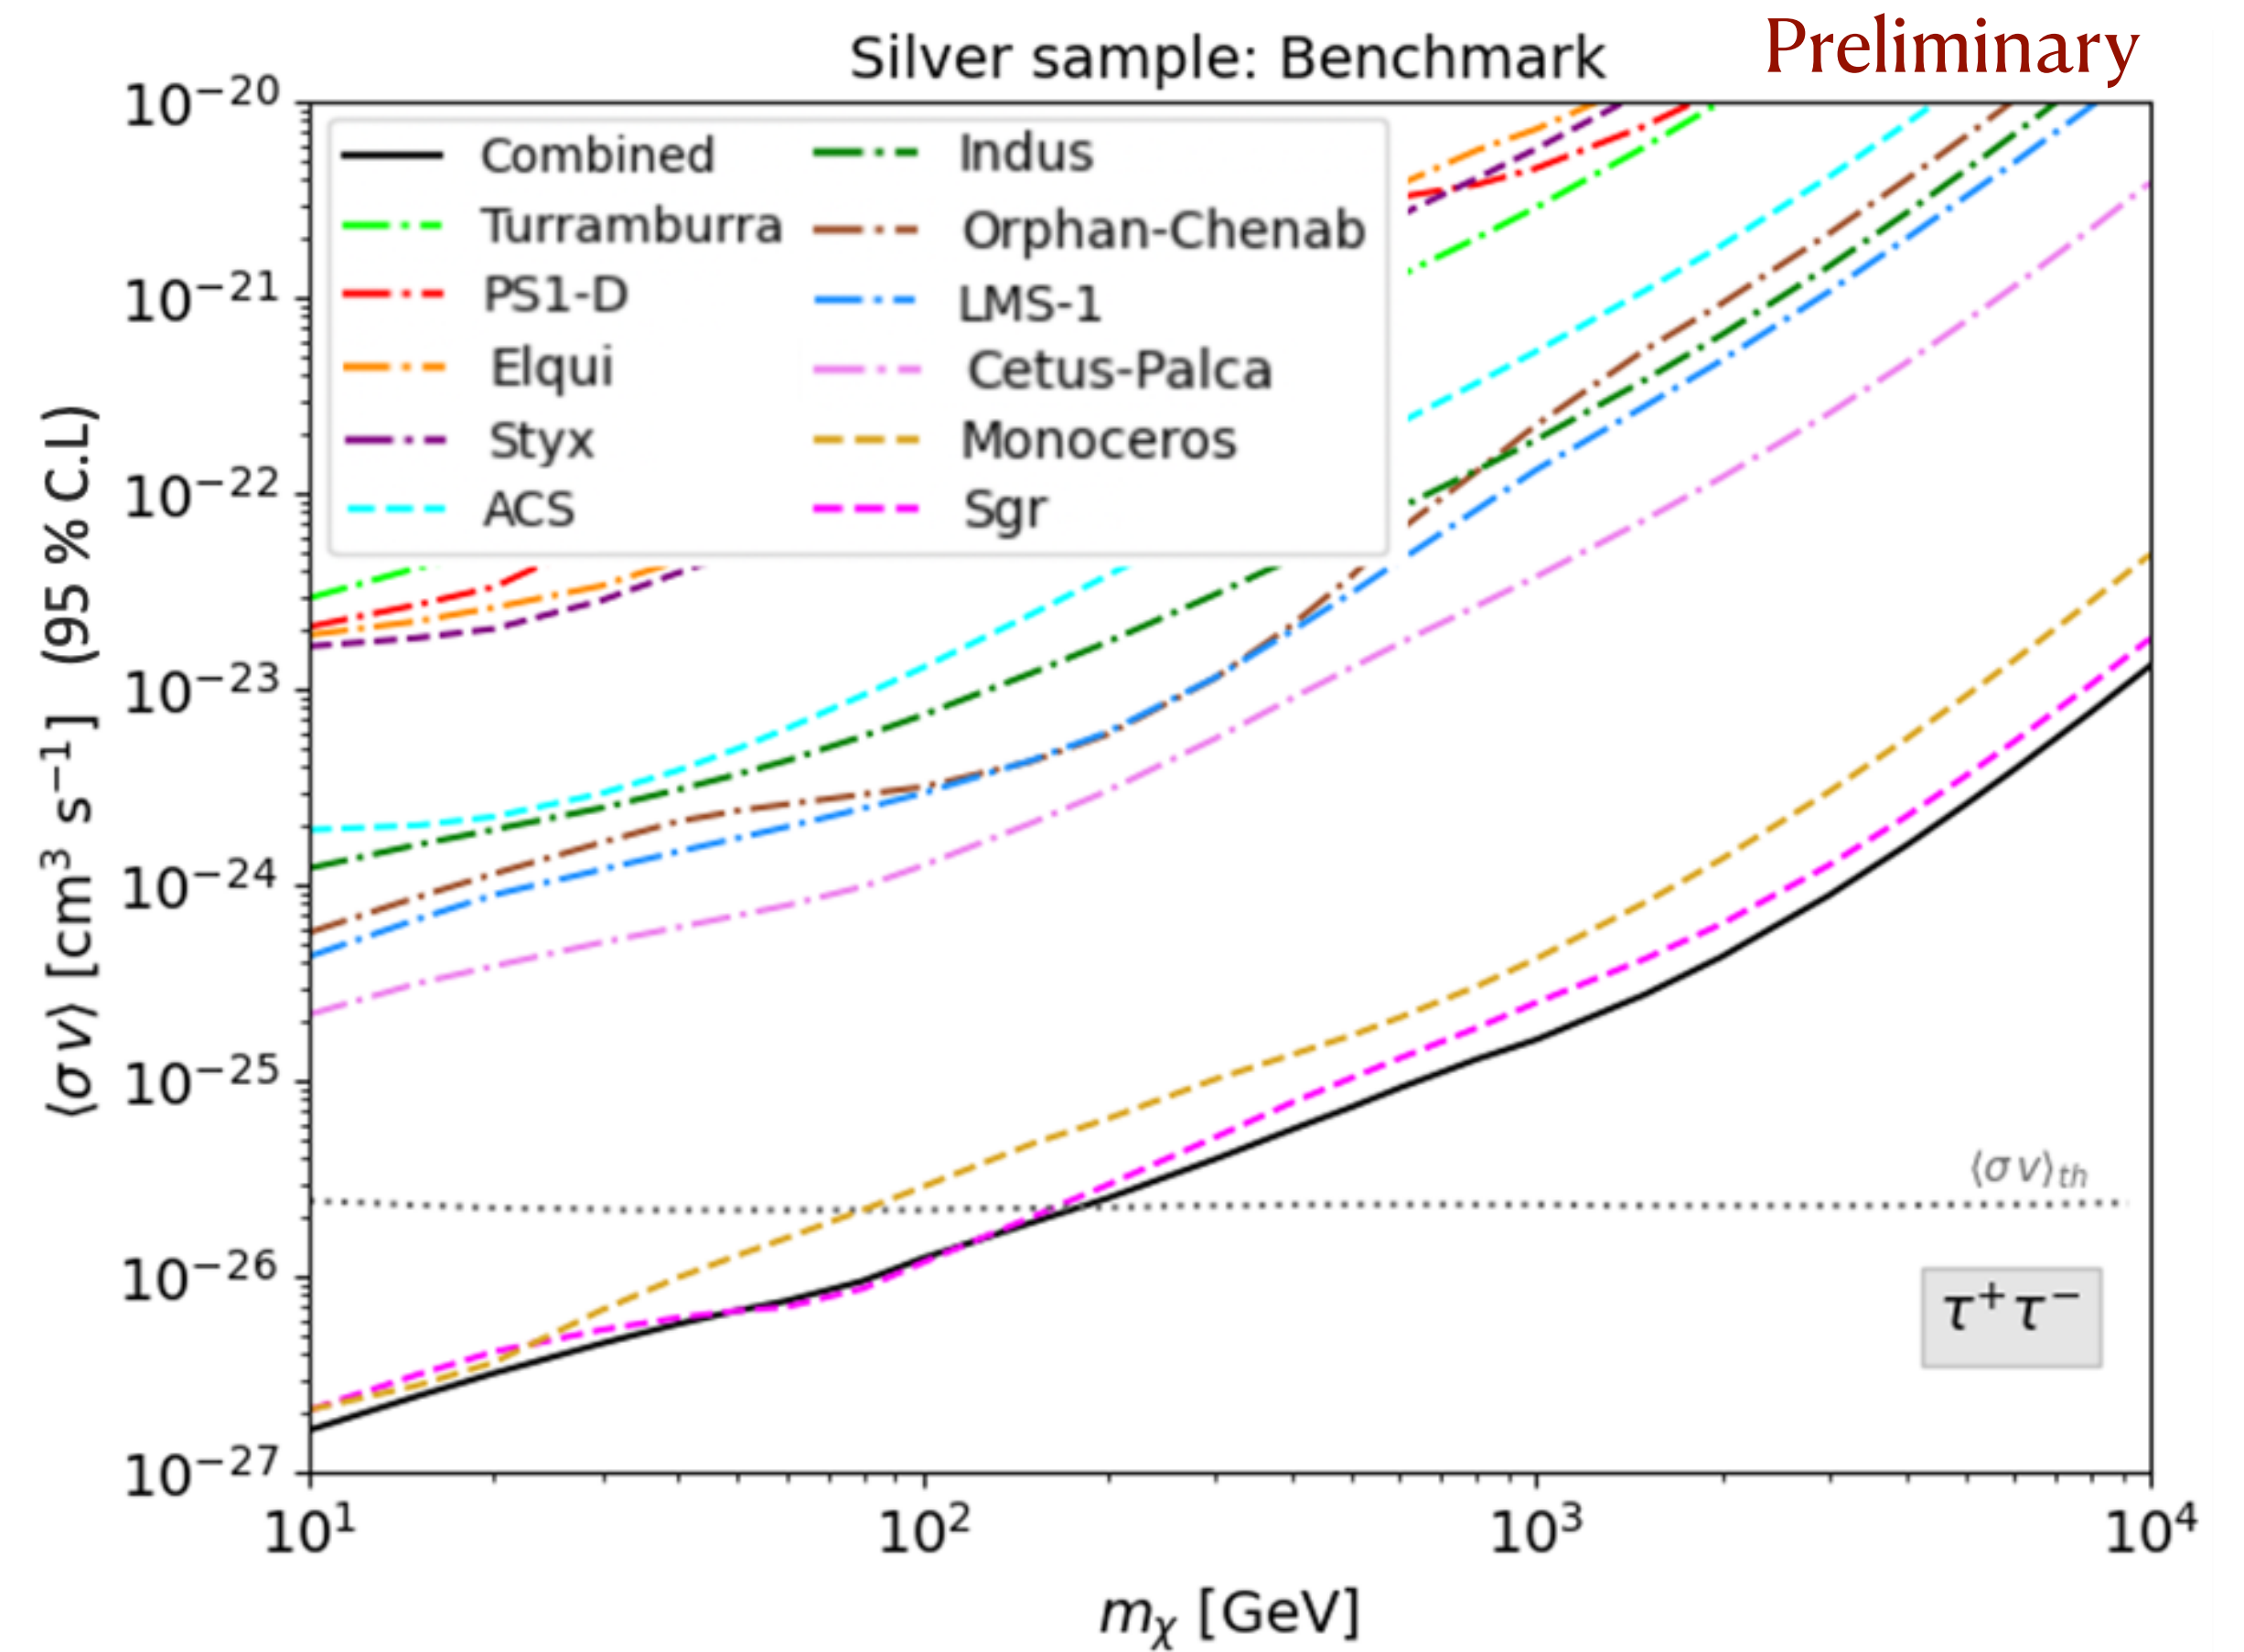

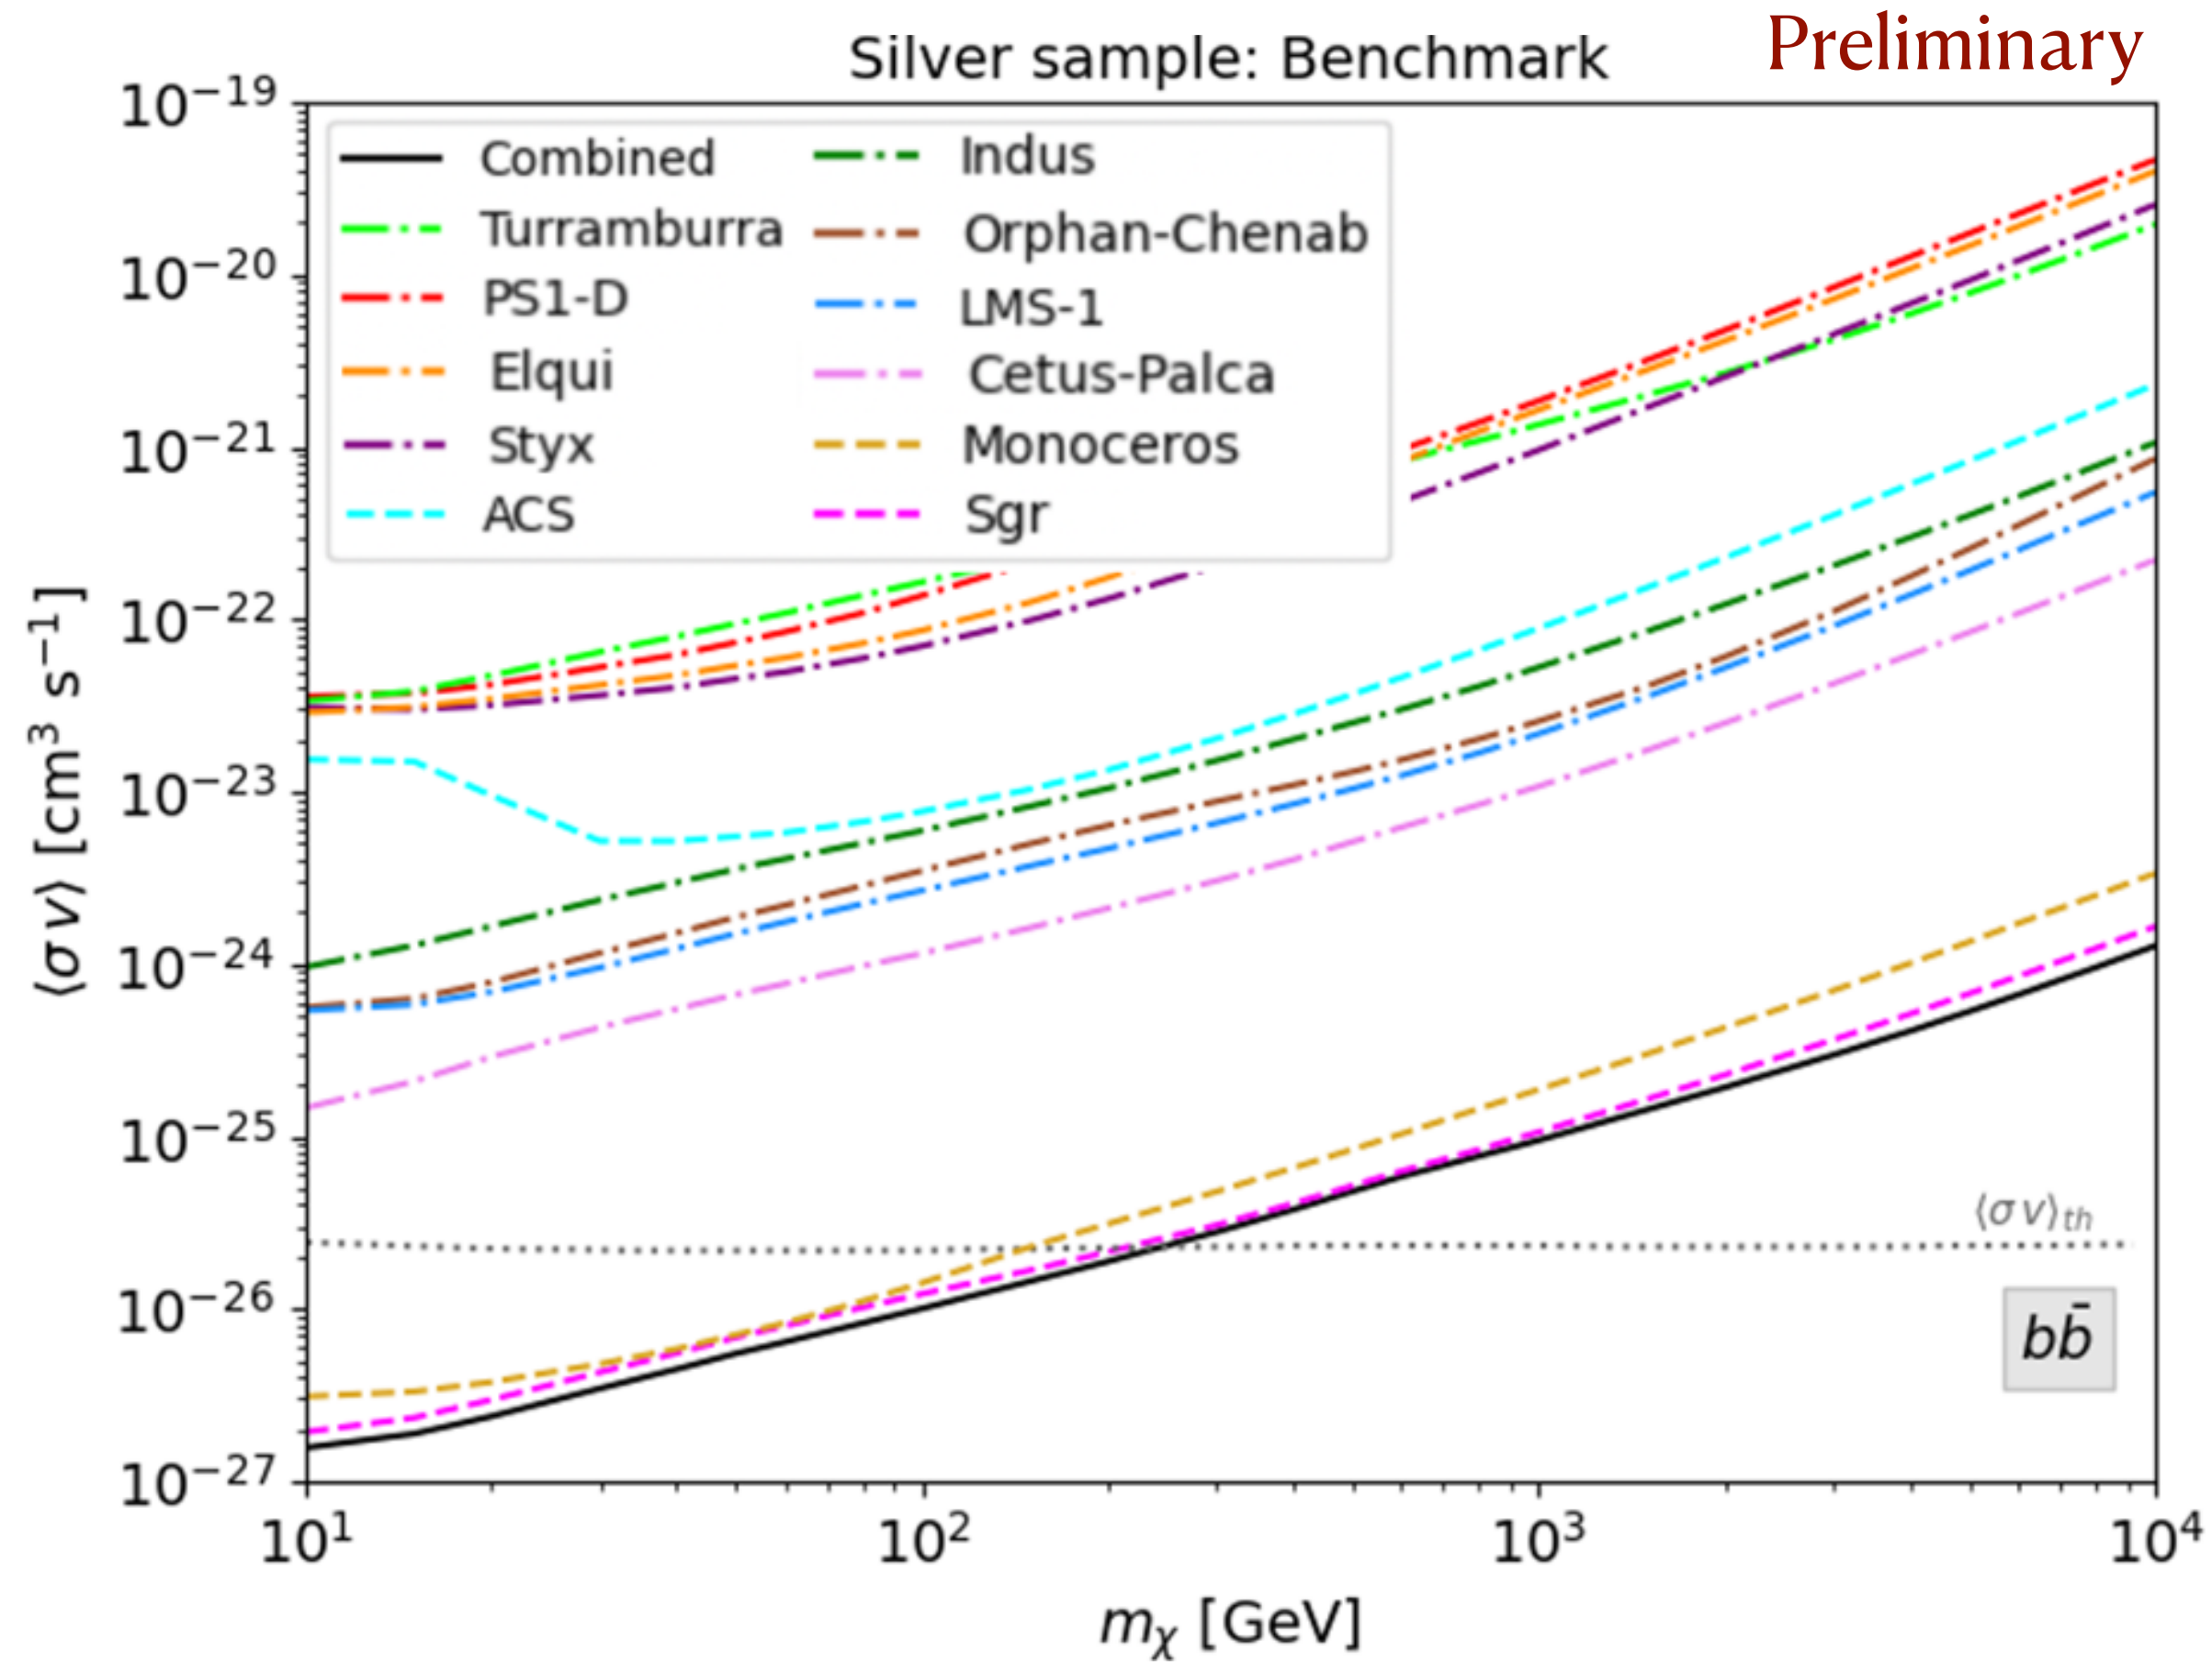

$$\log(\mathcal{L}_j(\mu, \theta_j | \mathcal{D}_j)) = \sum_i \log(\mathcal{L}_{i,j}(\mu, \theta_{i,j} | \mathcal{D}_{i,j}))$$

i : index of each target in the list
 j : index of each energy bin of the LAT data (\mathcal{D})

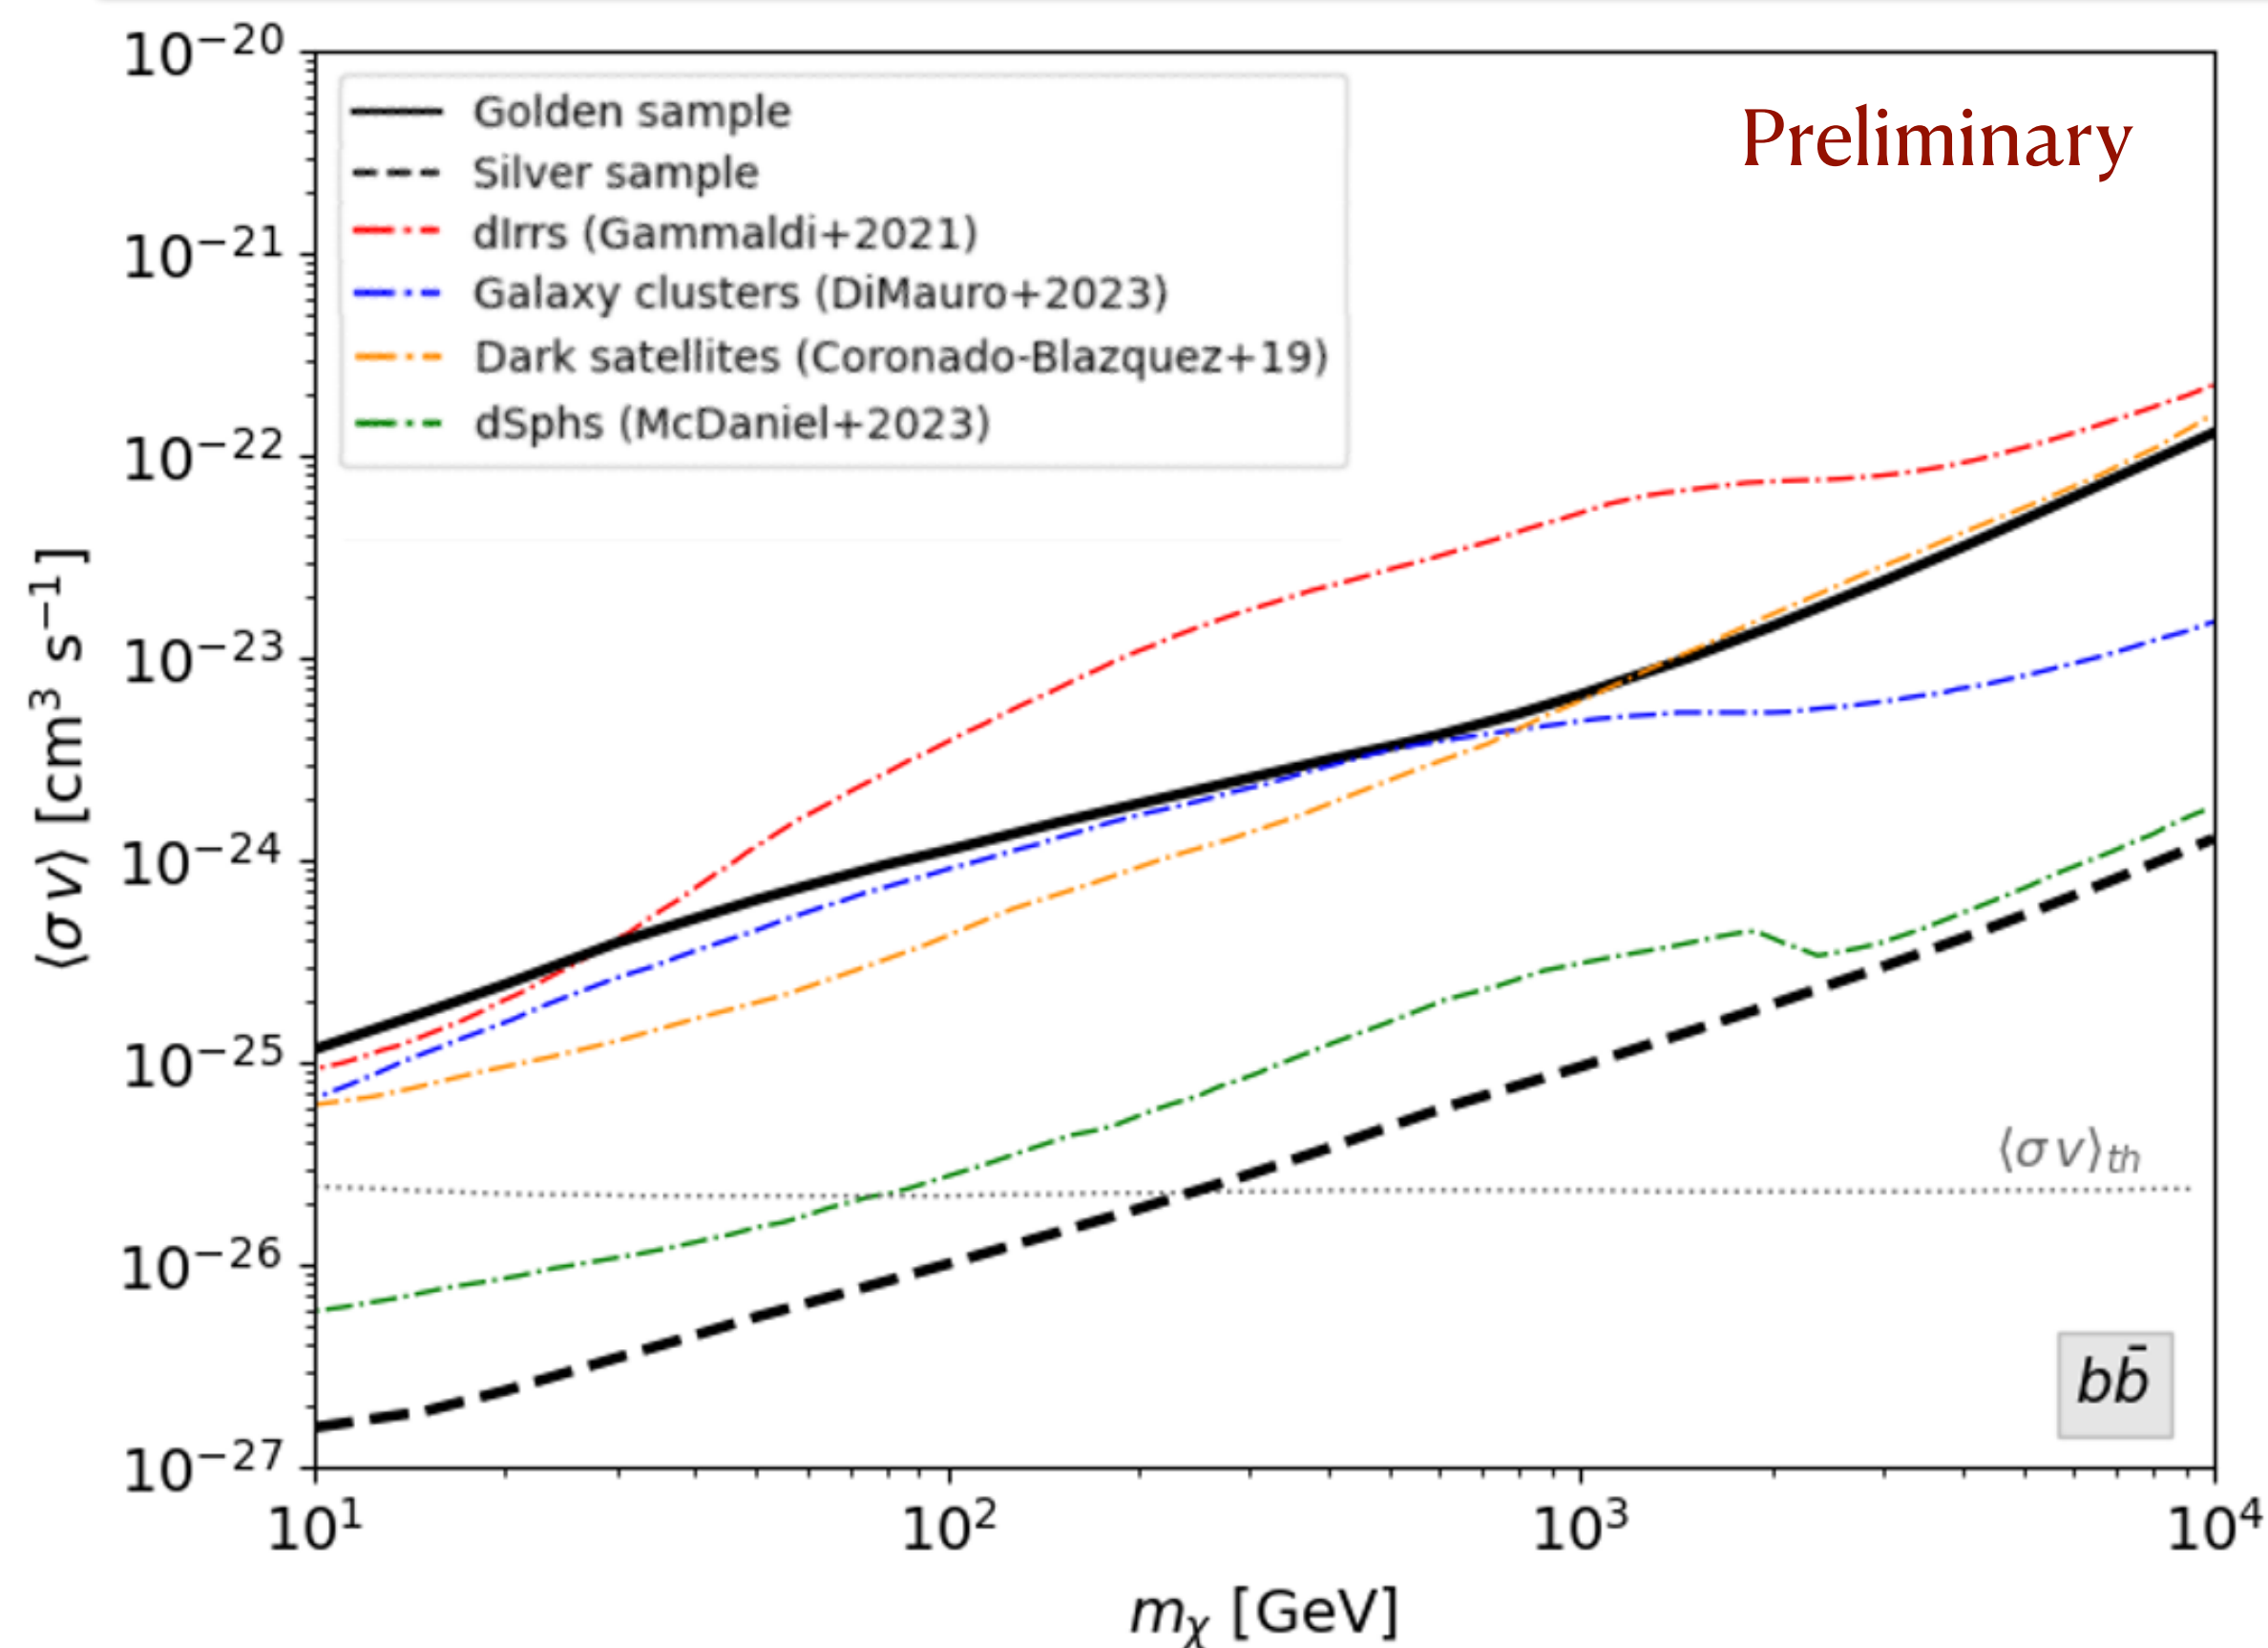

DM constraints: Golden Sample, M/L scenarios

DM constraints: Silver Sample, Benchmark case

DM constraints: Comparison with other targets

- * The results obtained for the golden sample of streams improve the limits achieved with dlrr galaxies, while they are similar to those for galaxy clusters and dark satellites.
- * At present, dSphs provide the most stringent constraints. However, when considering the silver sample of streams, the DM limits would be potentially comparable with them.

General Remarks

- * This work aims to provide a complementary target for indirect DM searches with gamma rays, potentially being as competitive as dSphs.
- * No detection after looking at 11 stellar streams.
- * The most reliable DM limits obtained (golden sample, benchmark scenario) are $\mathcal{O}(10)$ above the thermal relic cross-section for low WIMP masses for the $b\bar{b}$ and $\tau\bar{\tau}$ annihilation channels.

Caveats:

- The mass of the streams' core is currently uncertain. This could lead to overestimating or underestimating the J-factor, which would result into greater uncertainties of the DM limits. However, these uncertainties are expected to be contained within our M/L uncertainty band.
- High-resolution hydrodynamic simulations are needed to know the dynamic state of the core of each stream, as well as to accurately model their density profile accounting for tidal disruption. Work is already ongoing in this direction.

- * The work is about to be submitted to the journal.

Search of DM annihilation in Stellar Streams with the Fermi LAT
