## 2020 UPDATE OF THE EUROPEAN STRATEGY FOR PARTICLE PHYSICS

by the European Strategy Group

### 3 High-priority future initiatives

A. **An electron-positron Higgs factory is the highest-priority next collider.** For the longer term, the European particle physics community has the ambition to operate a proton-proton collider at the highest achievable energy. Accomplishing these compelling goals will require innovation and cutting-edge technology:

*• the particle physics community should ramp up its R&D effort focused on advanced accelerator technologies, in particular that for high-field superconducting magnets, including high-temperature superconductors;*

*• Europe, together with its international partners, should investigate the technical and financial feasibility of a future hadron collider at CERN with a centre-of-mass energy of at least 100 TeV and with an electron-positron Higgs and electroweak factory as a possible first stage. Such a feasibility study of the colliders and related infrastructure should be established as a global endeavour and be completed on the timescale of the next Strategy update.*

*The timely realisation of the electron-positron International Linear Collider (ILC) in Japan would be compatible with this strategy and, in that case, the European particle physics community would wish to collaborate.*

FERMILAB-CONF-23-008  
SLAC-PUB-17717  
January 2023

### Report of the 2021 U.S. Community Study on the Future of Particle Physics (Snowmass 2021)

The proposed plans in five-year periods starting in 2025 are given below.

For the five-year period starting in 2025:

1. Prioritize the HL-LHC physics program, including auxiliary experiments,
2. Establish a targeted  $e^+e^-$  Higgs Factory Detector R&D program,
3. Develop an initial design for a first-stage TeV-scale Muon Collider in the U.S.,
4. Support critical Detector R&D towards EF multi-TeV colliders.

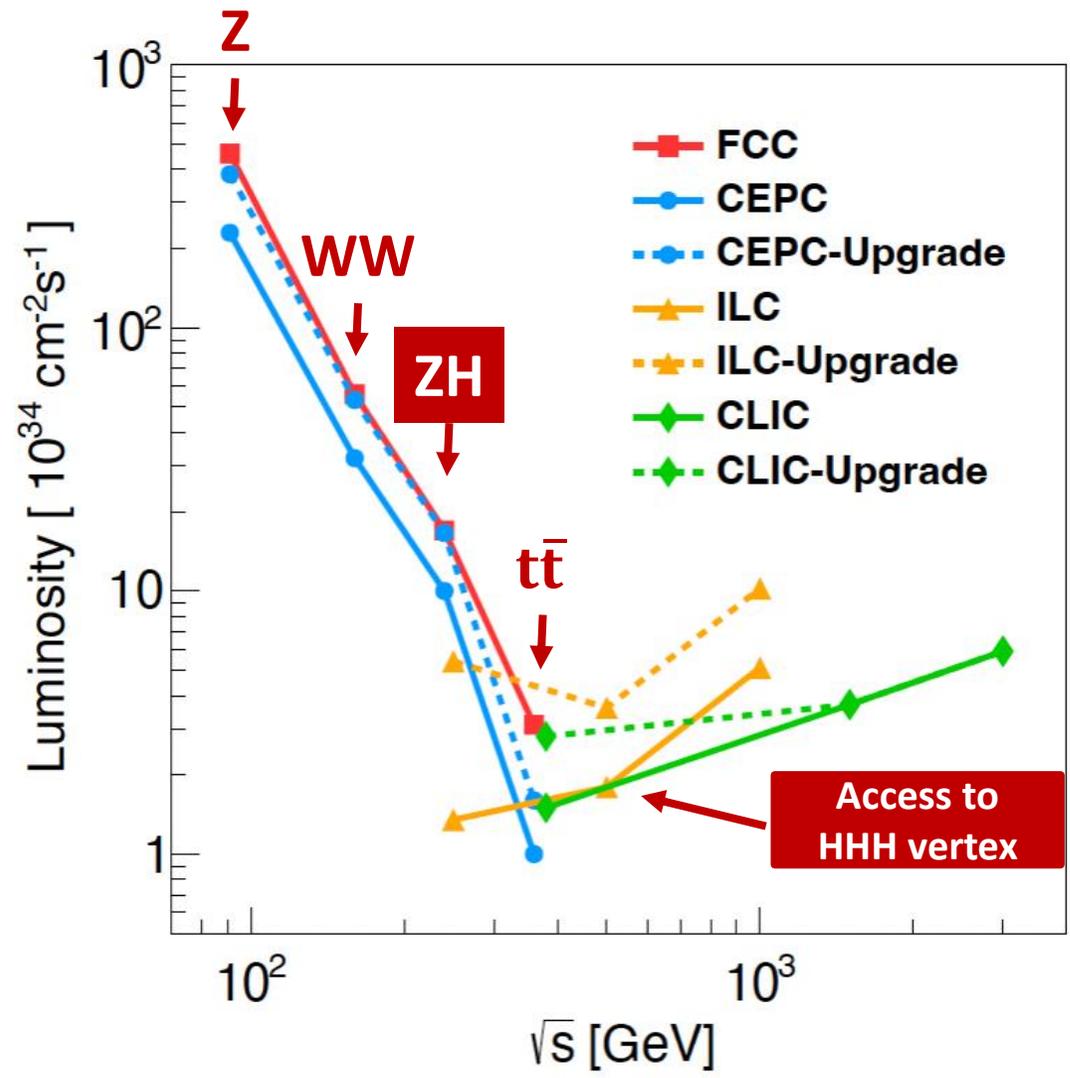

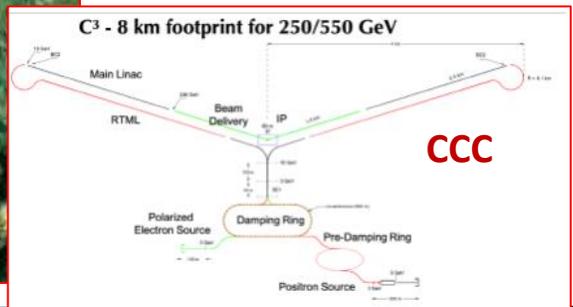

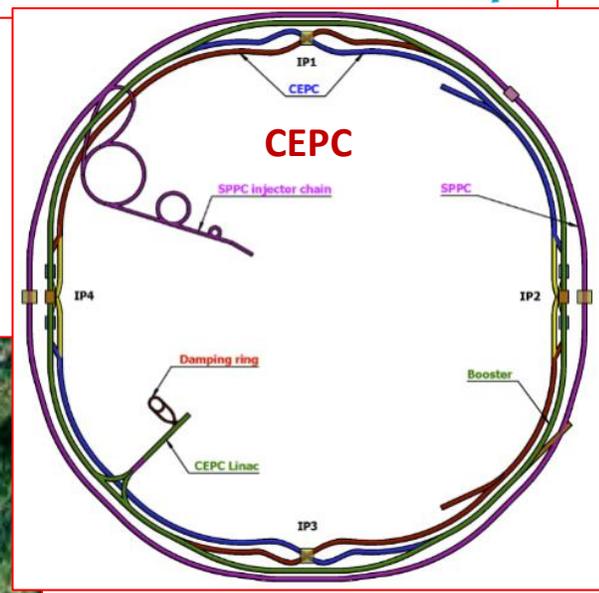

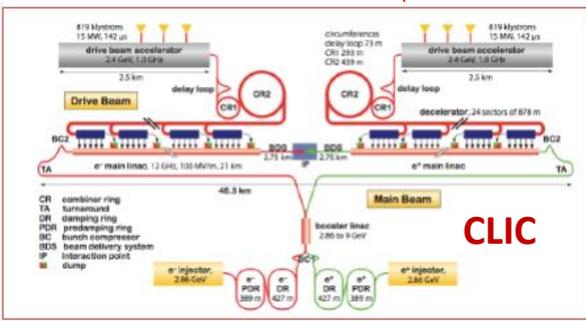

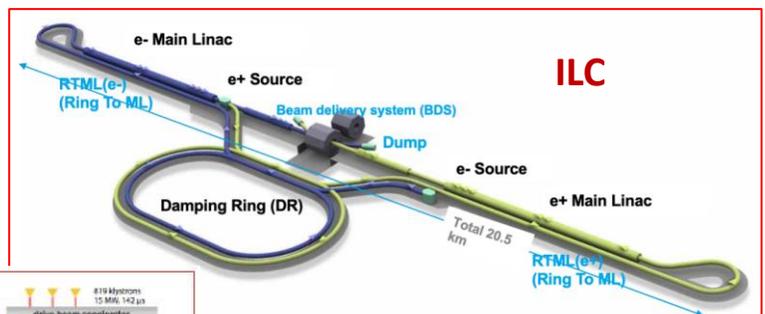

For the five-year period starting in 2030:

1. Continue strong support for the HL-LHC physics program,
2. Support the construction of an  $e^+e^-$  Higgs Factory,
3. Demonstrate principal risk mitigation for a first-stage TeV-scale Muon Collider.

Plan after 2035:

1. Continuing support of the HL-LHC physics program to the conclusion of archival measurements,
2. Support completing construction and establishing the physics program of the Higgs factory,
3. Demonstrate readiness to construct a first-stage TeV-scale Muon Collider,
4. Ramp up funding support for Detector R&D for energy frontier multi-TeV colliders.

# Future $e^+e^-$ colliders

Parameter	ILC		CLIC		
$\sqrt{s}$ [GeV]	250	500	380	1500	300
$L$ [ $10^{34}\text{cm}^{-2}\text{s}^{-1}$ ]	1.35	1.8	1.5	3.7	5.9
$L_{>99\%\sqrt{s}}$ [ $10^{34}\text{cm}^{-2}\text{s}^{-1}$ ]	1.0	1.0	0.9	1.4	2.0
Repetition frequency [Hz]	5		50		
Bunch separation [ns]	554		0.5		
Bunches per train	1312		352	312	
Beam size at IP $\sigma_x/\sigma_y$ [nm]	515/7.7	474/5.9	150/2.9	60/1.5	40/1
Crossing angle [mrad]	14		20		

## Linear colliders

- Very narrow beams: beamstrahlung reduces available center-of-mass energy
- CLIC almost continuous beam drives detector timing requirements
- Low duty cycles: triggerless readout, power cycling

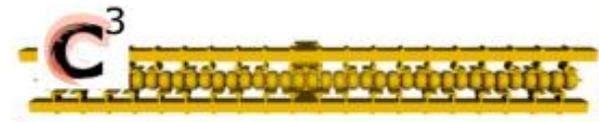

Parameter	FCCee (CEPC similar)			
$\sqrt{s}$ [GeV]	91.2	160	240	365
$L$ /IP [ $10^{34}\text{cm}^{-2}\text{s}^{-1}$ ]	182	19.4	7.3	1.33
Bunch separation [ns]	20	300	1000	6000
Bunches per beam	15880	880	248	40
$\sigma_x/\sigma_y$ [nm]	8/34	21/66	14/36	39/69
Crossing angle [mrad]	30			

## Circular colliders

- Transverse beam polarization: center-of-mass energy measurable at 1 ppm
- High luminosity and high cross section at Z peak drives detector rate capabilities and accuracy requirements
- **Beamstrahlung and synchrotron radiation dominate detector background**
- **Need to be minimized in Machine Detector Interface design**

# Future $e^+e^-$ colliders

- **ILC:**
  - Under consideration by the Japanese Ministry / Government as a **global project**
  - 2023: increased resources, ILC Technology Network established, incl. CERN (coordination for Europe)
- **FCC-ee:**
  - Feasibility study ongoing, very good progress in many areas, mid-term report expected in November 2023;
  - **Priority 1 for CERN / Europe (CERN Council)**
  - Outcome (technical feasibility, costs,...) decisive for Europe
- **CEPC:**
  - TDR in preparation, incl. cost review
  - A lot of progress on the technical side
  - **Aiming for approval in next 5-year plan (2025)**
  - Ranked 1<sup>st</sup> in Chinese HEP preselection
- **CLIC:**
  - Possible alternative for CERN
  - CLIC community is preparing a Project Readiness Report (PRR) for the next ESPP (2026/27)
- **CCC:**
  - R&D towards a demonstrator moving forward at SLAC;
  - Waiting for P5, and for a commitment of a laboratory to host it

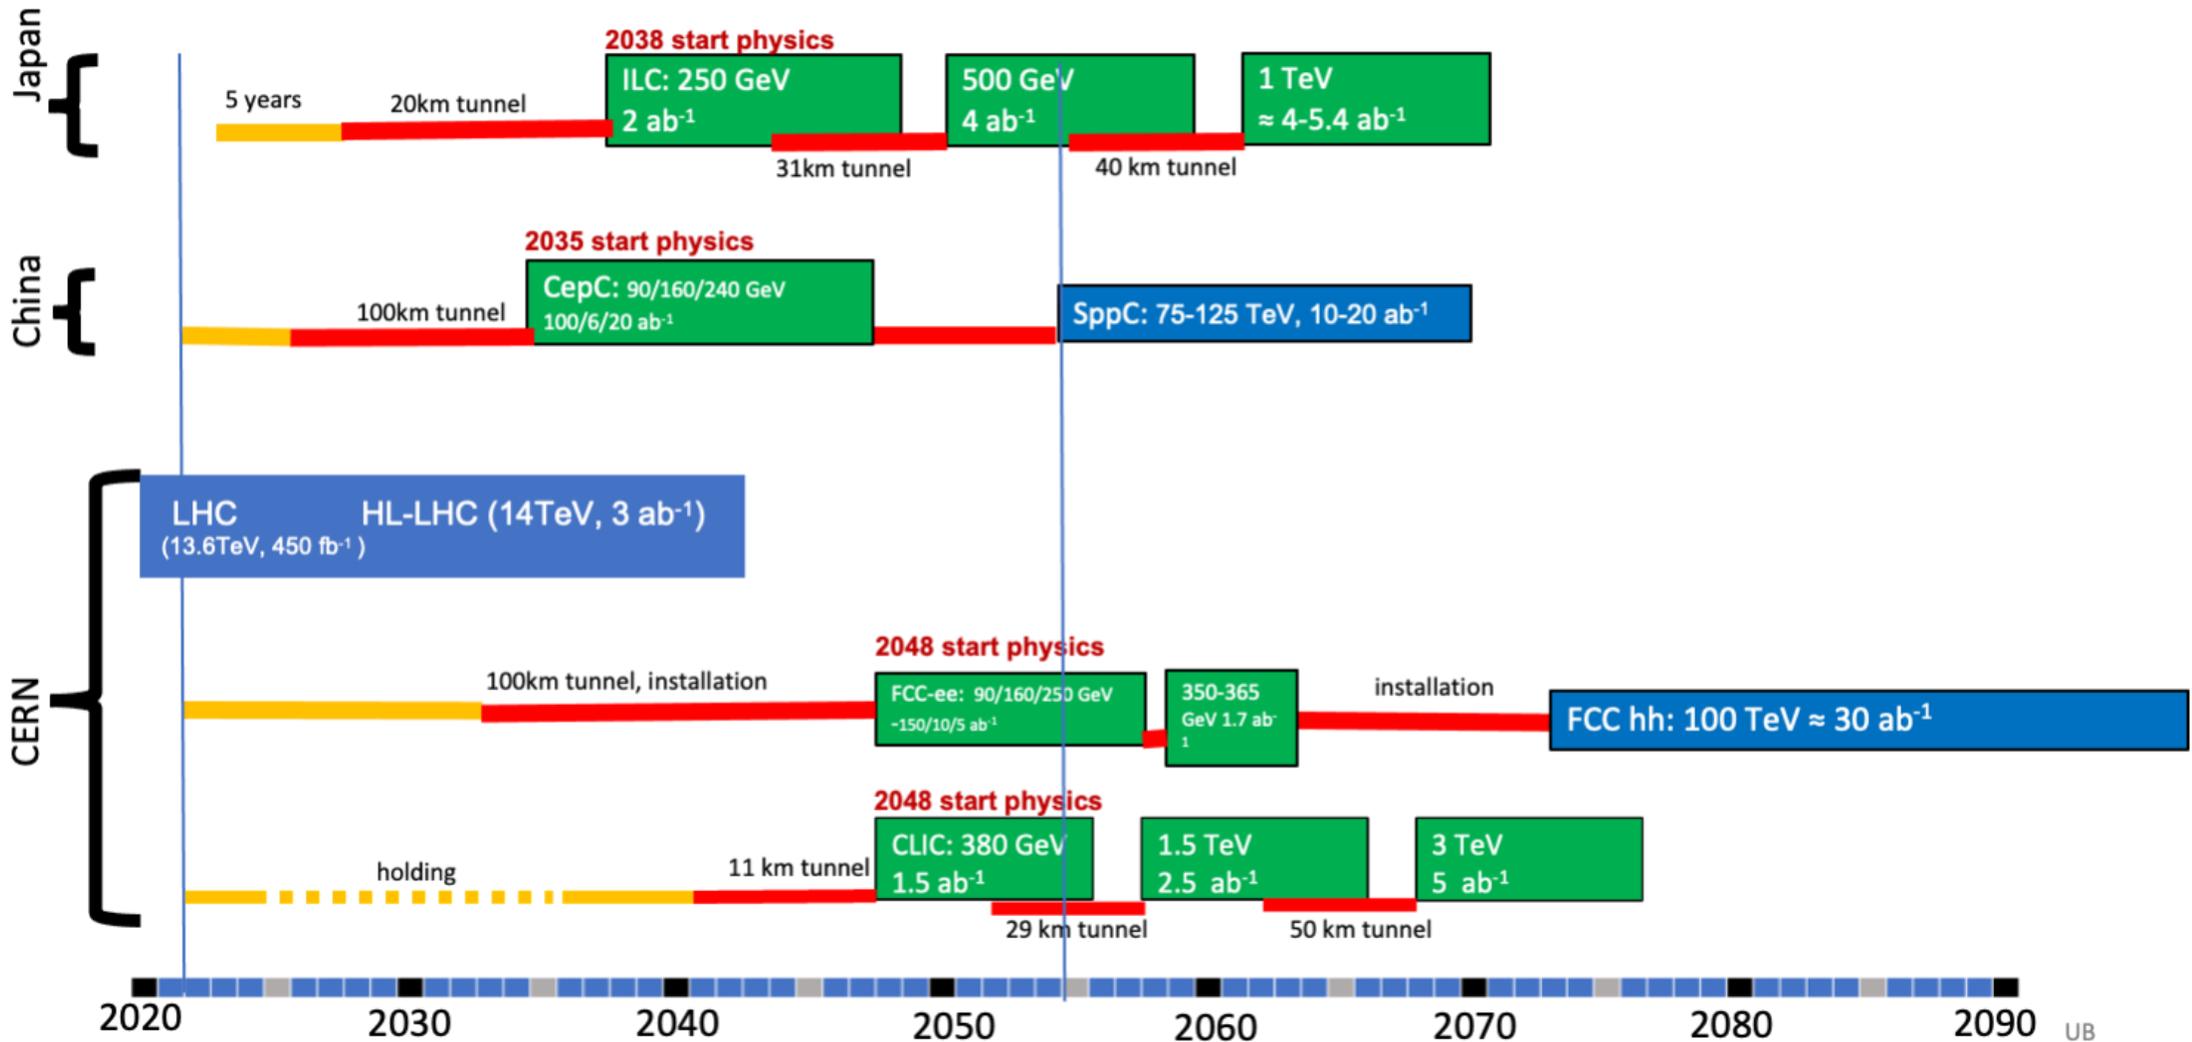

# Future $e^+e^-$ colliders

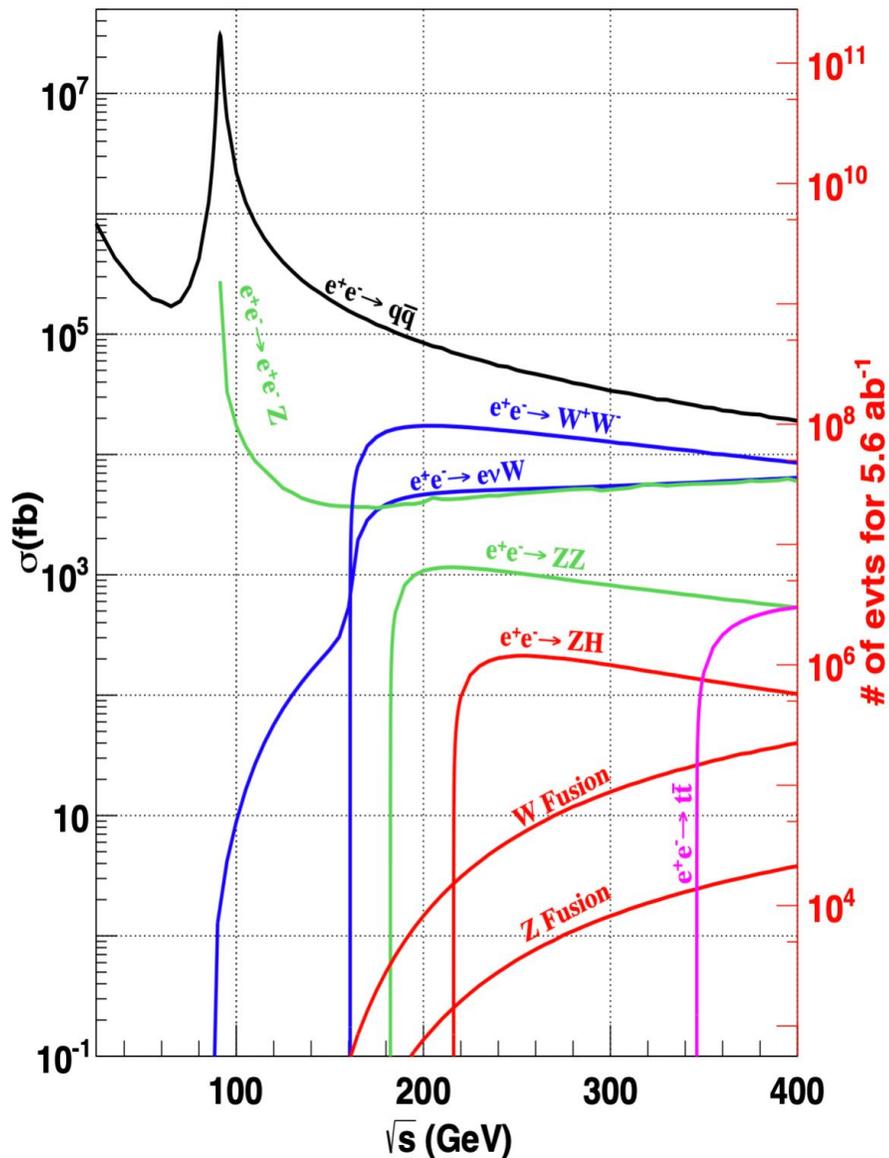

## Indicative scenarios of future colliders [considered by ESG]

- Proton collider
- Electron collider
- Muon collider
- Construction/Transformation
- Preparation / R&D

Original from ESG by UB  
Updated July 25, 2022 by MN

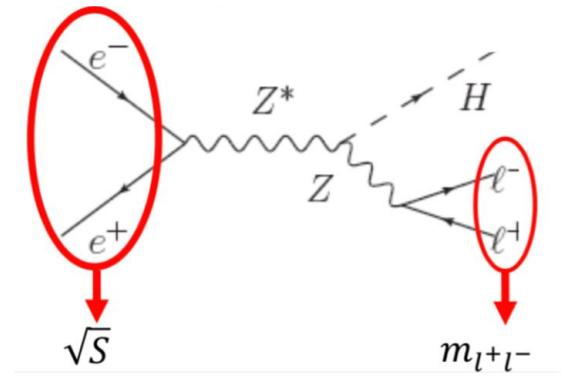

# Physics rates

- Main constraint from Z peak running at circular machines
  - highest luminosities, large cross section
  - physics rate  $\sim 100$  kHz
    - fast detector readout
    - triggerless readout may be challenging
    - zero suppression of data
    - occupancy at detector  $O(\text{Hz}/\text{cm}^2)$
  - down to 100 Hz at  $\sqrt{s} = 160$  GeV
- $O(10$  kHz) Bhabha scattering

- Higgs identification from the Z recoil mass
- Higgs mass measurement from recoil mass peak
  - target is  $\sigma_{m_h} \sim \Gamma_h \sim 4 \text{ MeV}$
  - achievable if  $\frac{\sigma_{p_t}}{p_t^2} = 2 \times 10^{-5} \text{ GeV}^{-1}$
  - or  $\frac{\sigma_{p_t}}{p_t} \sim 10^{-3}$  at 45 GeV

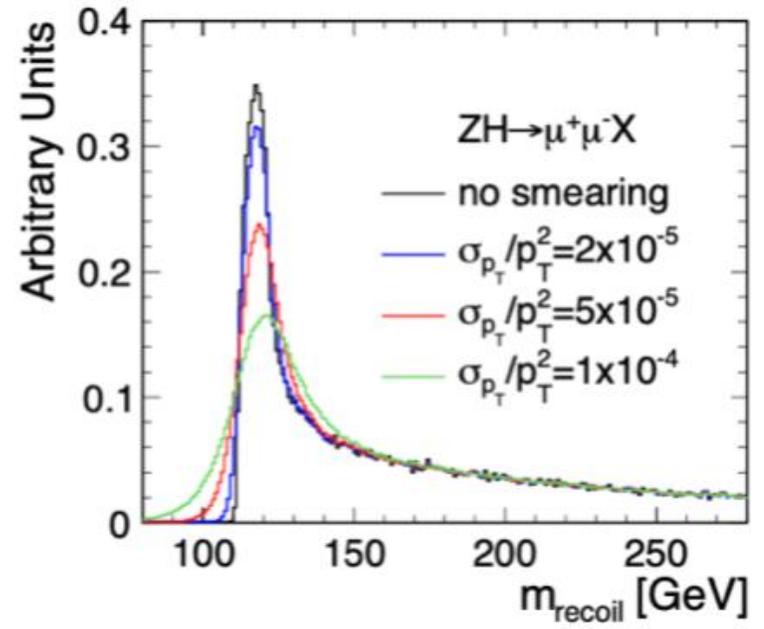

$$m_{\text{recoil}}^2 = (\sqrt{s} - E_{l\bar{l}})^2 - p_{l\bar{l}}^2 = s - 2E_{l\bar{l}}\sqrt{s} + m_{l\bar{l}}^2$$

- Monitoring of the Beam Energy Spread if
 
$$\frac{\sigma_{p_t}}{p_t} < BES$$

$$BES = 0.16\% (\sqrt{s} = 250 \text{ GeV}), 0.13\% (\sqrt{s} = 91.2 \text{ GeV})$$

- $\sigma_{m_{ll}} \ll \Gamma_Z = 2.5 \text{ GeV}$ 
  - no smearing of physical Z peak width

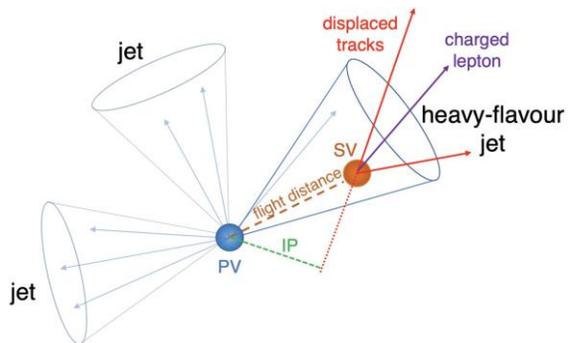

# Physics requirements: position resolution

- Higgs identification from the Z recoil mass
- Model independent measurements of  $BR(H \rightarrow b\bar{b}), BR(H \rightarrow c\bar{c}), BR(H \rightarrow gg)$ 
  - Difficult measurement at LHC
- Use of secondary vertices and displaced tracks

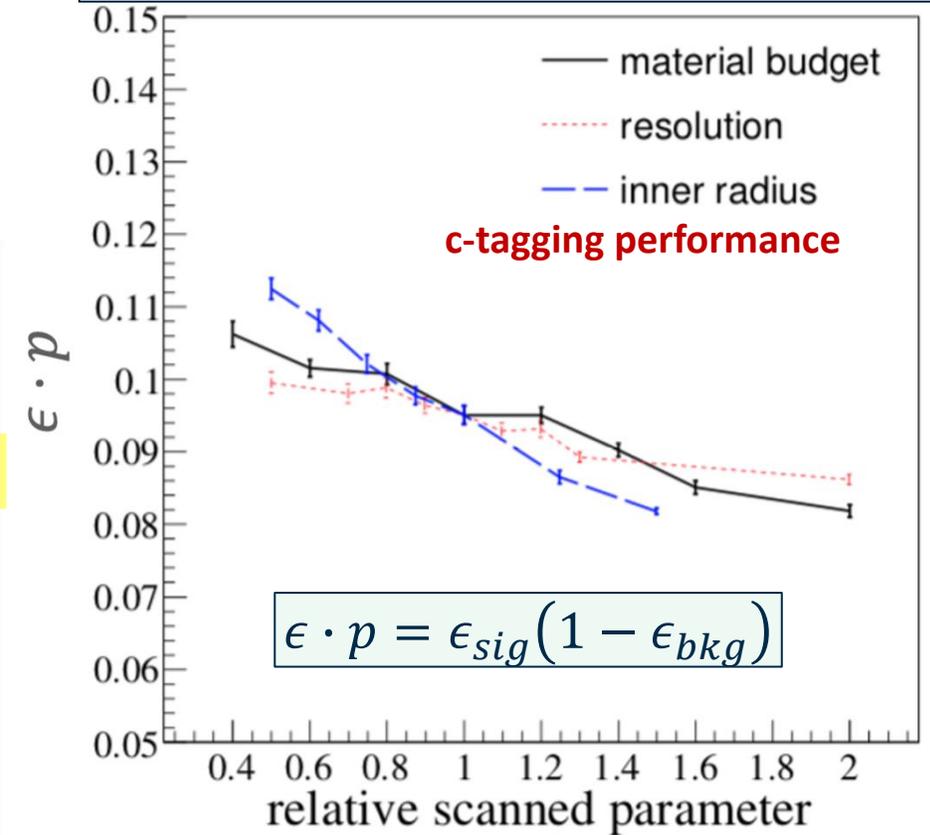

- require good impact parameter resolution

$$\sigma_{d_0} = a \oplus \frac{b}{p \sin^2 \theta}, \quad a = 5 \mu\text{m}, b = 15 \mu\text{m} \cdot \text{GeV}$$

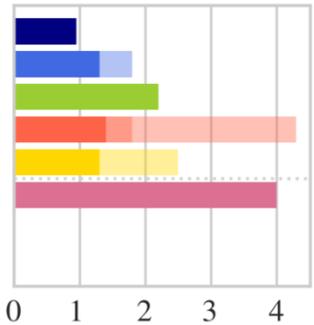

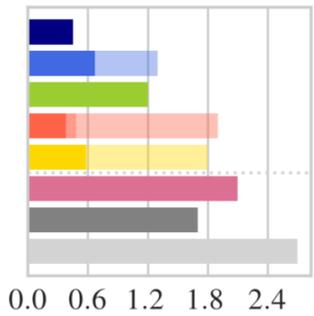

- $b$  more critical than  $a$ : optimize  $X_0, R_{in}$

Manqi Ruan at ECFA Topical workshop on tracking and vertexing 2023 and JHEP 11 (2022) 100  
M. Selvaggi at FCC Week, London 2023

	Scenario A (Aggressive)	Scenario B (Baseline)	Scenario C (Conservative)
Material per layer/ $X_0$	0.075	0.15	0.3
Spatial resolution/ $\mu\text{m}$	1.4 - 3	2.8 - 6	5 - 10.7
$R_{in}/\text{mm}$	8	16	23

FCC-ee240

de Blas et al., 1905.03764

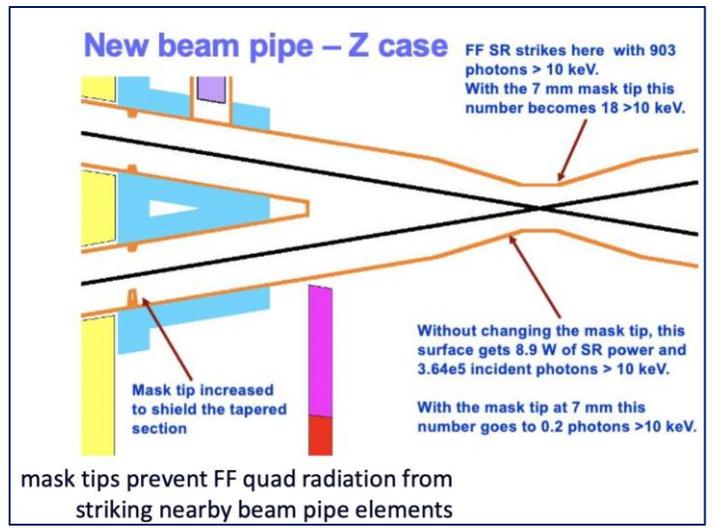

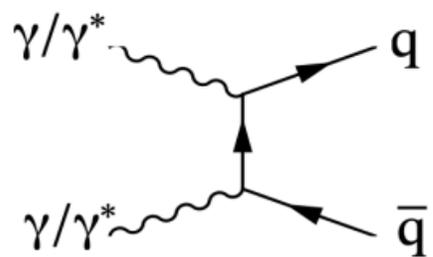

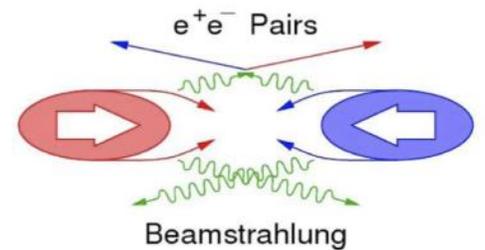

- A Z-factory is also a  $\tau$ ,  $c$ ,  $b$  factory
- Particle Identification is essential for many physics measurements
- Needed on a wide momentum range
  - $B_s^0 \rightarrow D_s K$  has K up to 30 GeV/c
  - K for flavour tagging in  $b \rightarrow c \rightarrow s$  decay chains are pretty soft
  - useful in tau physics for  $V_{us}$  measurements in  $\tau \rightarrow K\nu$

Particle	Tera-Z	Belle II	LHCb
<b>b hadrons</b>			
$B^+$	$6 \times 10^{10}$	$3 \times 10^{10}$ (50 ab <sup>-1</sup> on $\Upsilon(4S)$ )	$3 \times 10^{13}$
$B^0$	$6 \times 10^{10}$	$3 \times 10^{10}$ (50 ab <sup>-1</sup> on $\Upsilon(4S)$ )	$3 \times 10^{13}$
$B_s$	$2 \times 10^{10}$	$3 \times 10^8$ (5 ab <sup>-1</sup> on $\Upsilon(5S)$ )	$8 \times 10^{12}$
b baryons	$1 \times 10^{10}$		$1 \times 10^{13}$
$\Lambda_b$	$1 \times 10^{10}$		$1 \times 10^{13}$
<b>c hadrons</b>			
$D^0$	$2 \times 10^{11}$		
$D^+$	$6 \times 10^{10}$		
$D_s^+$	$3 \times 10^{10}$		
$\Lambda_c^+$	$2 \times 10^{10}$		
$\tau^+$	$3 \times 10^{10}$	$5 \times 10^{10}$ (50 ab <sup>-1</sup> on $\Upsilon(4S)$ )	

# Machine Backgrounds

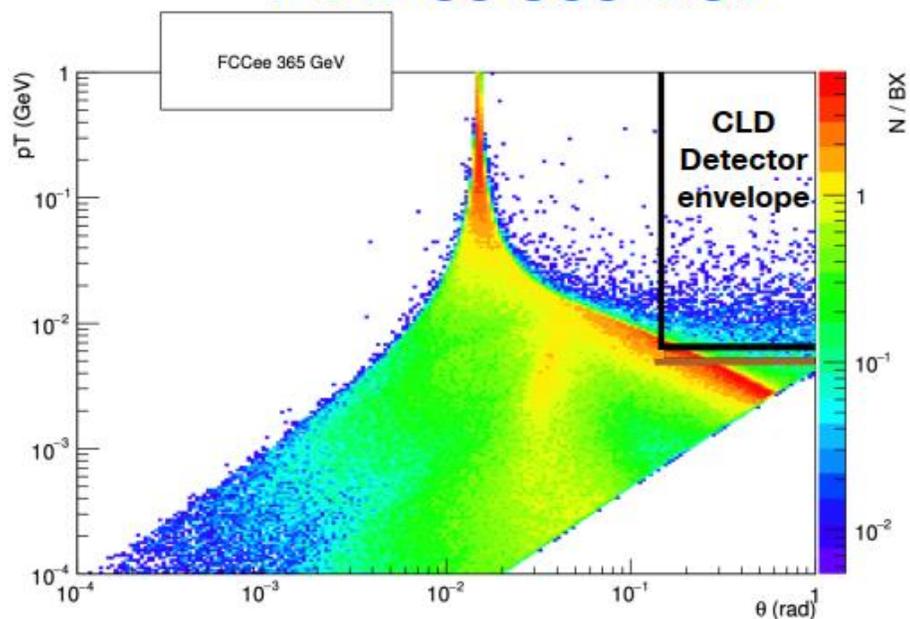

- Most relevant backgrounds at  $e^+e^-$  machines:
  - beamstrahlung (photons)
  - incoherent pair production ( $e^+e^-$ )
    - can lead to occupancy and energy in the detector
    - impact on space granularity, timing information
    - design of inner part of the detector
  - $\gamma\gamma \rightarrow q\bar{q}$  (hadrons)
  - synchrotron radiation (photons)
    - shielding in MDI
    - limits solenoid B-field
  - usually increasing with energy
- May sum up to count rates of 10-50 MHz/cm<sup>2</sup>
- Radiation doses  $O(100 \text{ kRad/yr}) - O(10^{11} n_{eq}/\text{yr})$

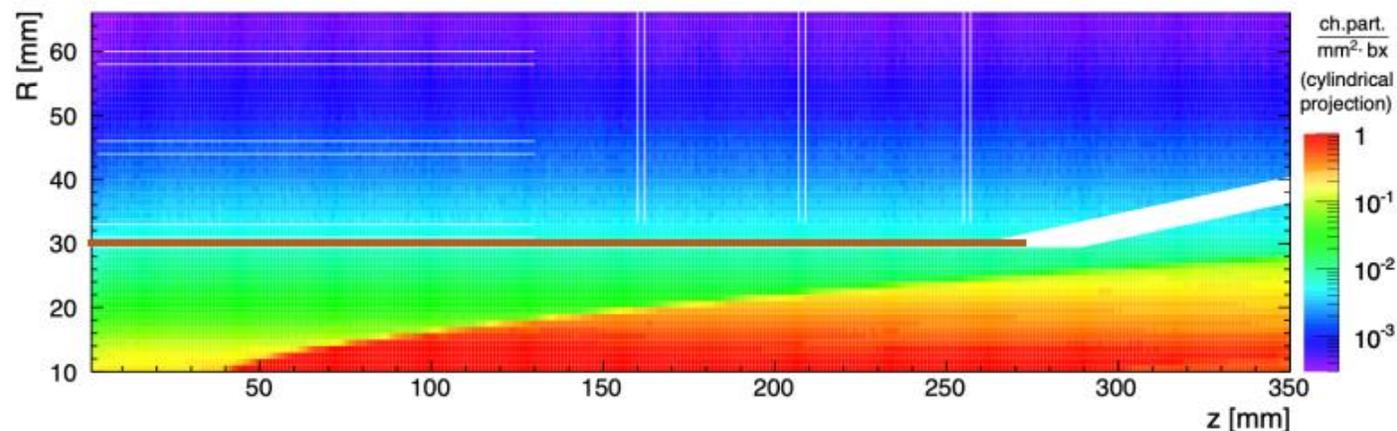

# Machine Backgrounds

- Large flux of scattered ee pairs spiralling in main solenoid's field **determines radius of beam pipe** (envelope of high- $p_T$  component)
  - **CLIC** ( $B=4T$ ,  $\sqrt{s} = 3 \text{ TeV}$ ) : 30 mm
  - **ILC** ( $B=3.5-5T$ ,  $\sqrt{s} = 500 \text{ GeV}$ ) : 16 mm
  - **FCC-ee** ( $B=2T$ ,  $\sqrt{s} = 365 \text{ GeV}$ ) : 10 mm

FCC-ee 365 GeV

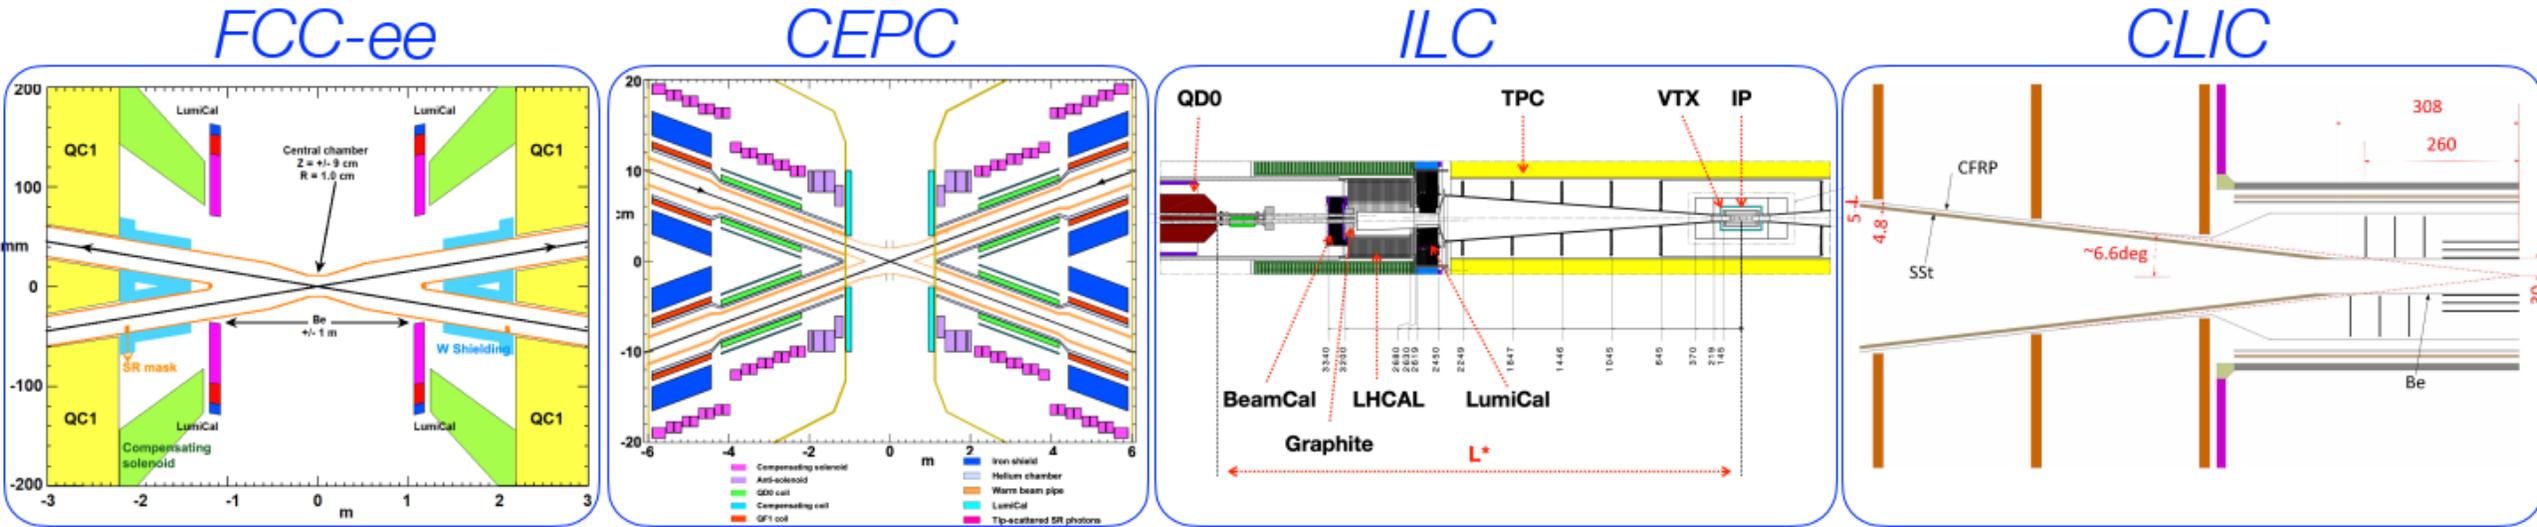

CLIC 3 TeV

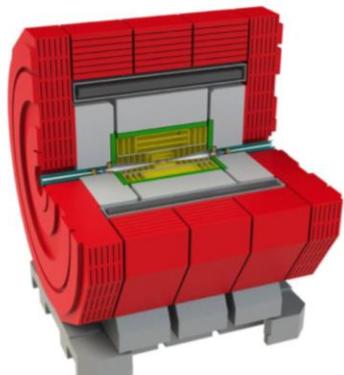

G. Marchiori at ECFA Topical workshop on tracking and vertexing 2023

# Interaction regions

	FCC-ee	CEPC	ILC	CLIC
$L^*$ ( $\Delta z$ between IP and first)	2.2 m	2.2 m	4.1 m	6 m
Position of final quadrupole	Inside detector	Inside detector	Outside detector	Outside detector
LumiCal position	$z=1$ m, $\sim 50$ -100 mrad (Constrained by compensating solenoid)	$z \sim 0.95$ -1.11 m 26-105 mrad (fiducial volume 53-79 mrad)	$z=2.5$ m, 33-80 mrad	$z=2.5$ m, 39-134 mrad
Tracker acceptance	Down to $\sim 9$ degrees (defined by luminometer)	Down to $\sim 8$ degrees	Down to $\sim 6^\circ$ (defined by conical beam pipe)	Down to $\sim 7^\circ$ (defined by conical beam pipe)
Inner beam pipe radius	10 mm	10 mm	16 mm	29.4 mm
Crossing angle	30 mrad	33 mrad	14 mrad	20 mrad
Main solenoid B field	2T	3T (2T at Z pole)	3.5-5T	4T

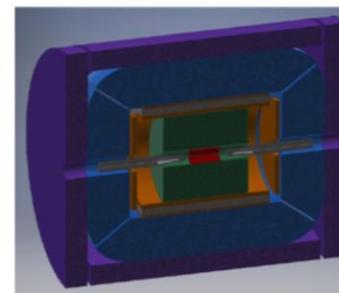

# Detector layouts

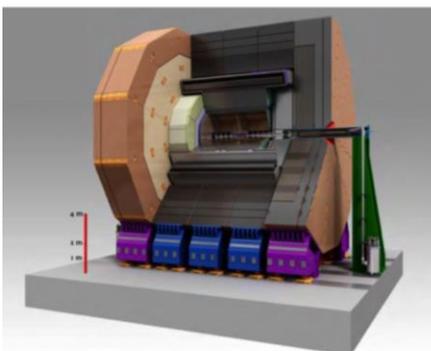

**CLIC** => **CLICdet**,  
vs: 380 GeV, 1.5 TeV, 3 TeV

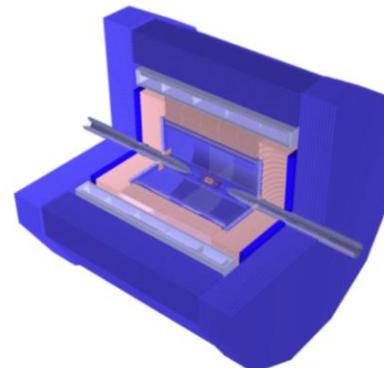

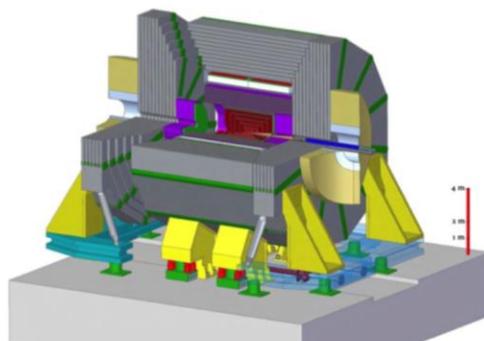

**FCC-ee** => **CLD** and **IDEA**  
vs: 90 - 365 GeV

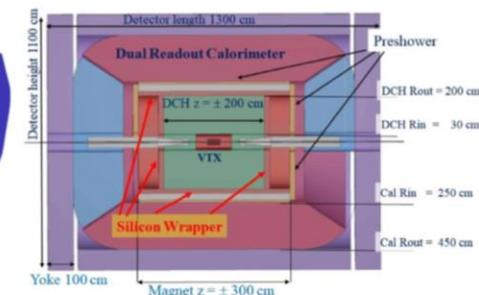

**ALLEGRO**

**ILC** => **ILD** and **SiD**:  
vs: 250 – 500 GeV (1 TeV)

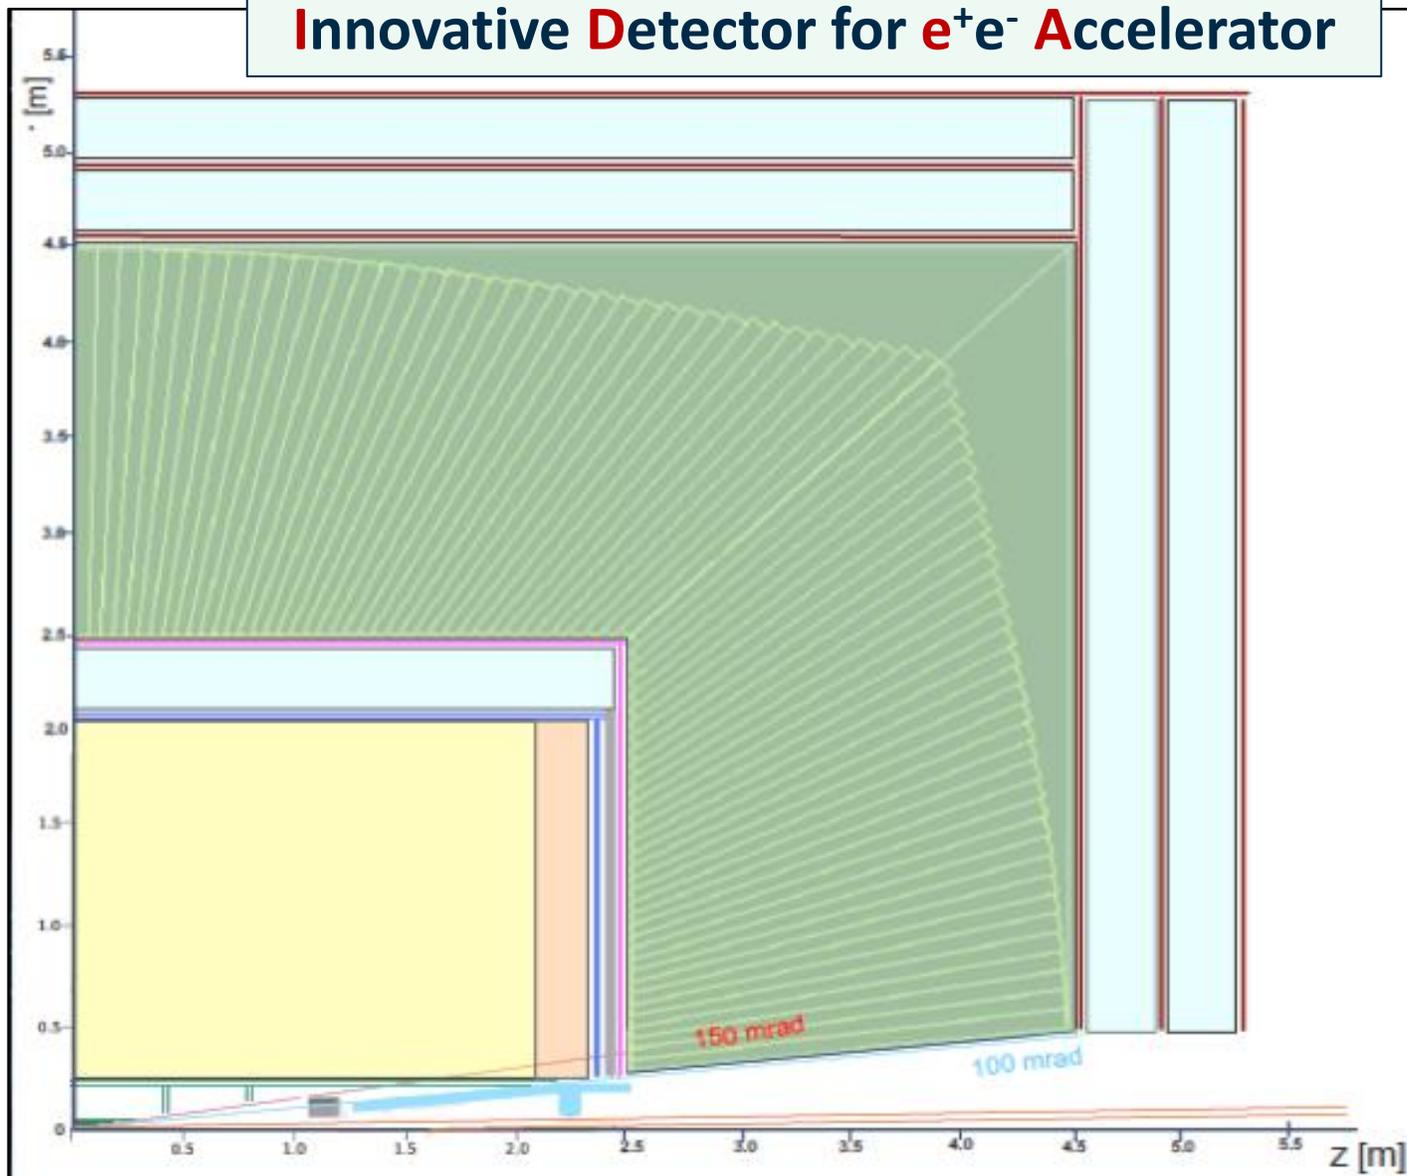

**CEPC** => **baseline** and **low-B**  
vs: 90-240 GeV

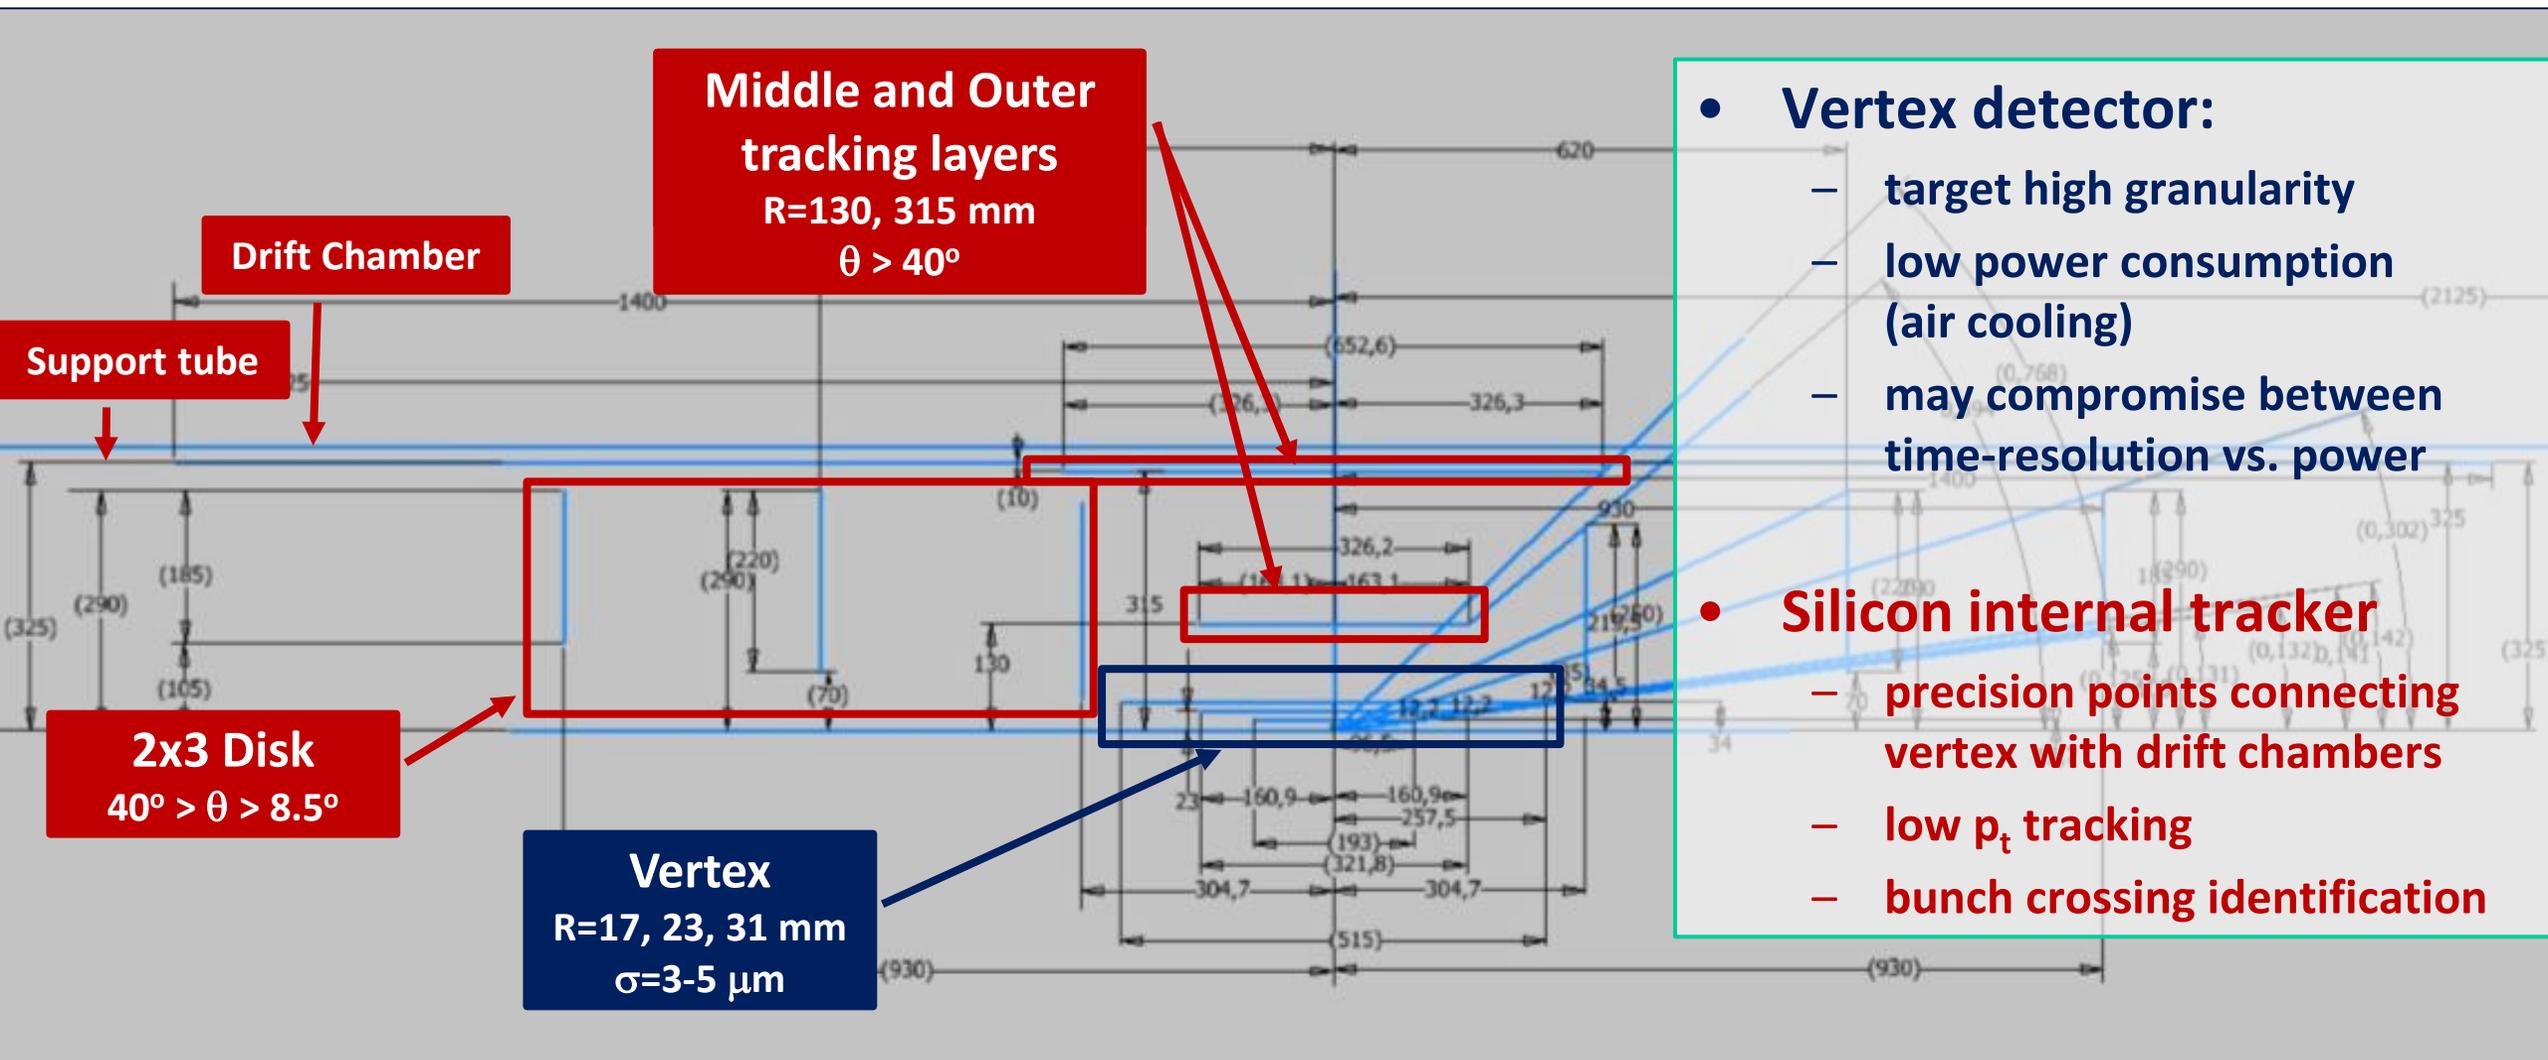

Collider	ILC		CLIC	FCC-ee			CEPC	
Detector Concept	SiD	ILD	CLICdet	CLD	FCC-ee IDEA	Noble LAr/LKr	CEPC baseline	CEPC IDEA

# The IDEA Concept

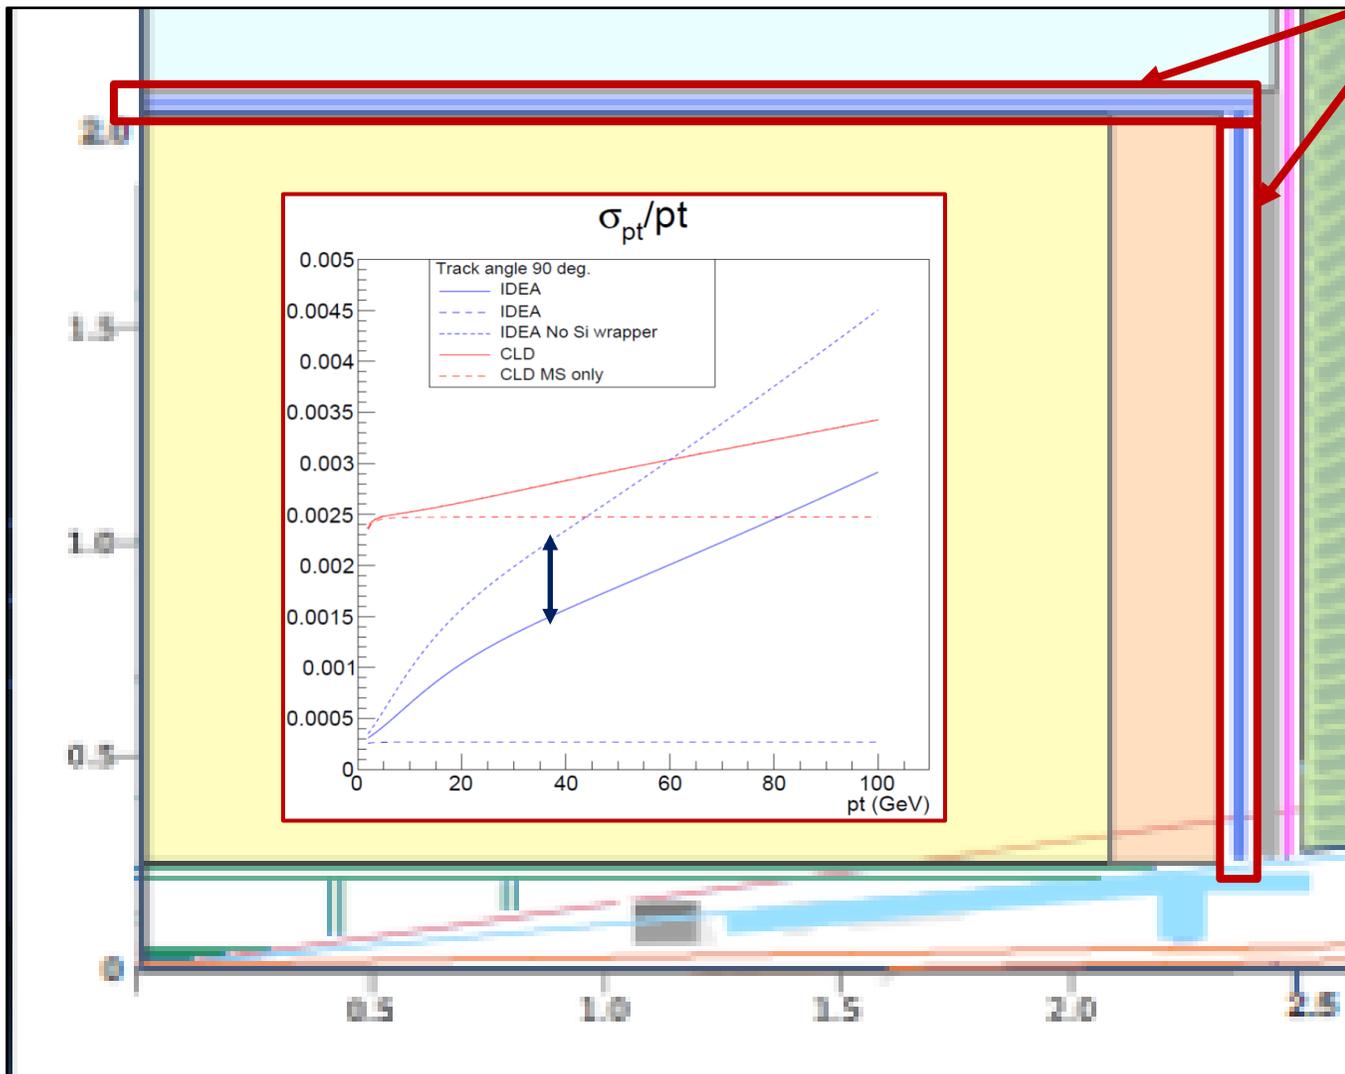

## Innovative Detector for $e^+e^-$ Accelerator

- Central tracking device:
  - light Drift CHamber
- **Silicon detectors for precision measurements**
  - **vertex detector**
  - **silicon internal tracker**
  - **silicon wrapper/TOF**
- Thin solenoid with 2T field (according to MDI limits)
- Dual readout calorimeter
  - supplemented by a pre-shower detector
- Muon chambers in the solenoid return yoke

# The IDEA Concept: Si Wrapper

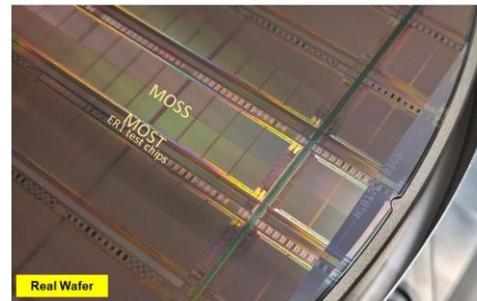

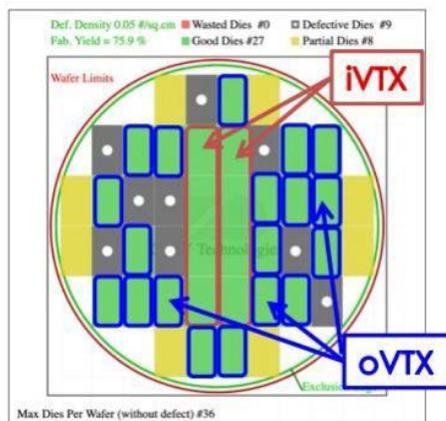

- **Precision silicon layer around the central tracker**

- improve momentum resolution
- define  $\theta$  resolution and acceptance
- extend tracking coverage in the **forward/backward region** by providing an additional point to particles with few measurements in the drift chamber
- precise and stable ruler for acceptance definition

- Covered area  $\sim 90 \text{ m}^2$

- important impact on services
- technology suitable for large size production

- In general focus on **depleted monolithic CMOS detectors**
    - High-Voltage/High-Resistivity CMOS processes commercially available
    - Depleted region provide fast rising and "high-amplitude" signals
    - No need of the complex and costly interconnection technique used in hybrid detectors
    - DRD7.6 support TPSCo 65 nm (ITS3) and LFoundry 110 nm (ARCADIA)
    - Low power to operate in the vertex region with air cooling
    - target 0.15%  $X_0$ /layer: develop self supporting structures integrating multiple chips
    - open issue: do we need **time stamping at the Z pole?**
- I'll not go into many details: many presentations already developed these points

*ITS3: next ALICE upgrade for the Inner Tracking System*

- TaichuPix3: full size CMOS sensor (1024×512 pixels)
  - TowerJazz 180 nm CIS process
  - 25×25  $\mu\text{m}^2$  pixels
  - Column-drain readout
  - Triggerless mode: 3.84 Gbps data interface
  - Triggered mode: data match with trigger time-stamp

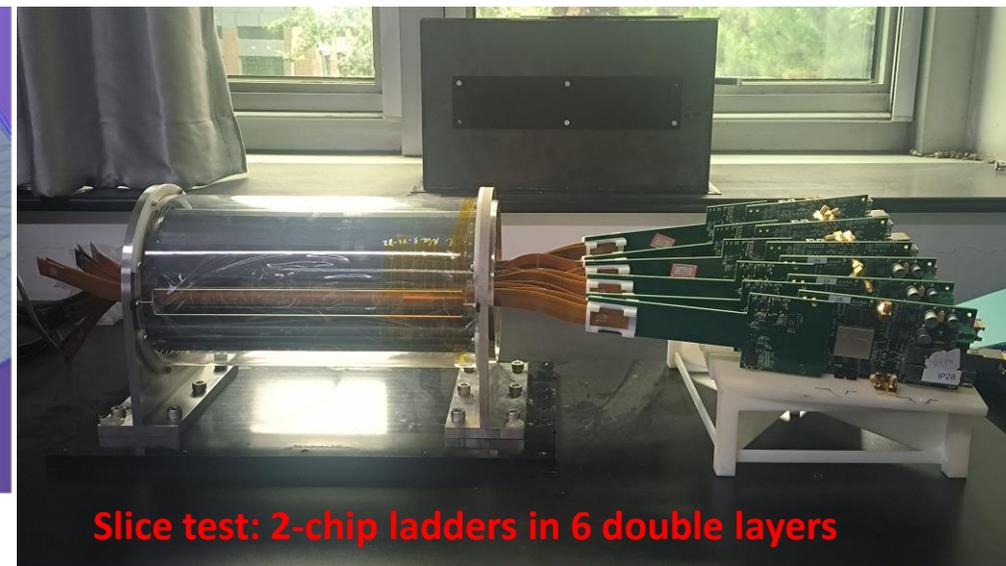

TaichuPix-3 chip vs. coin

- Resolution:
  - Laser test  $\sim 4 \mu\text{m}$
  - Test beams  $\sim 4.8 \mu\text{m}$
  - (required 3-5  $\mu\text{m}$ )
- Radiation hardness
  - $> 3 \text{ MRad}$
  - required  $> 1 \text{ MRad}$

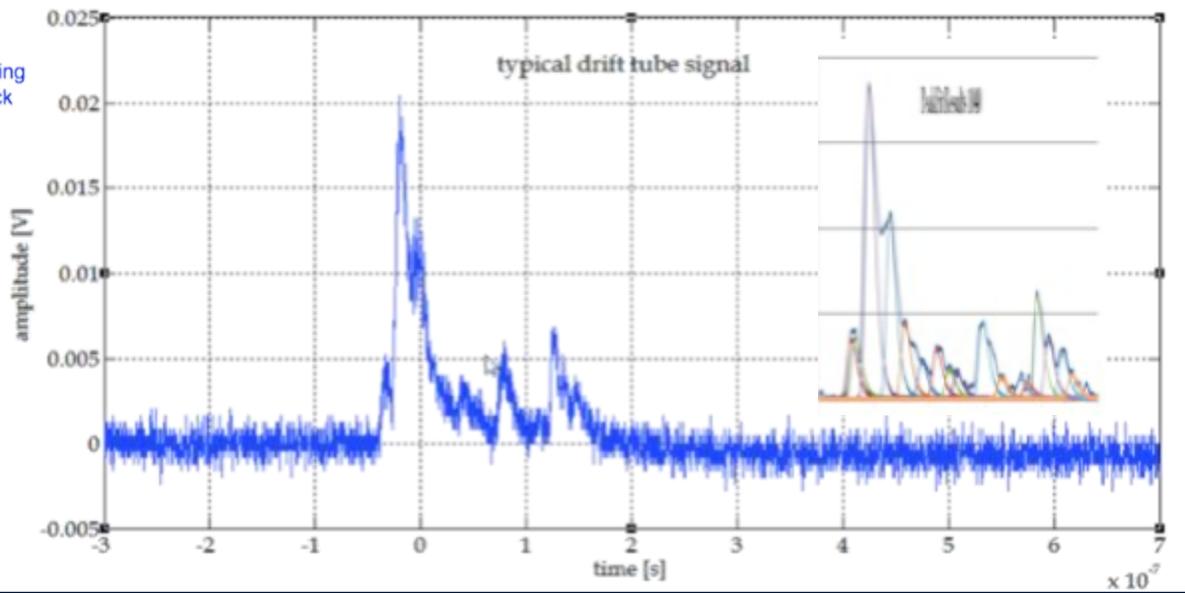

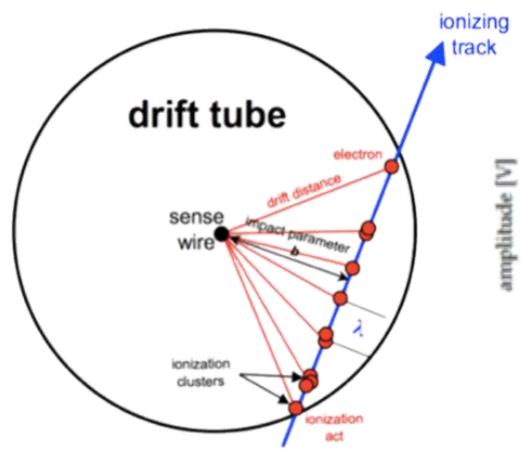

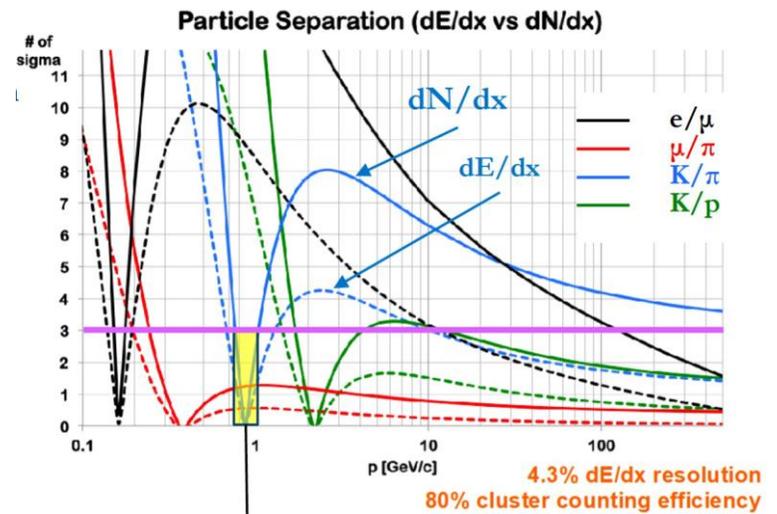

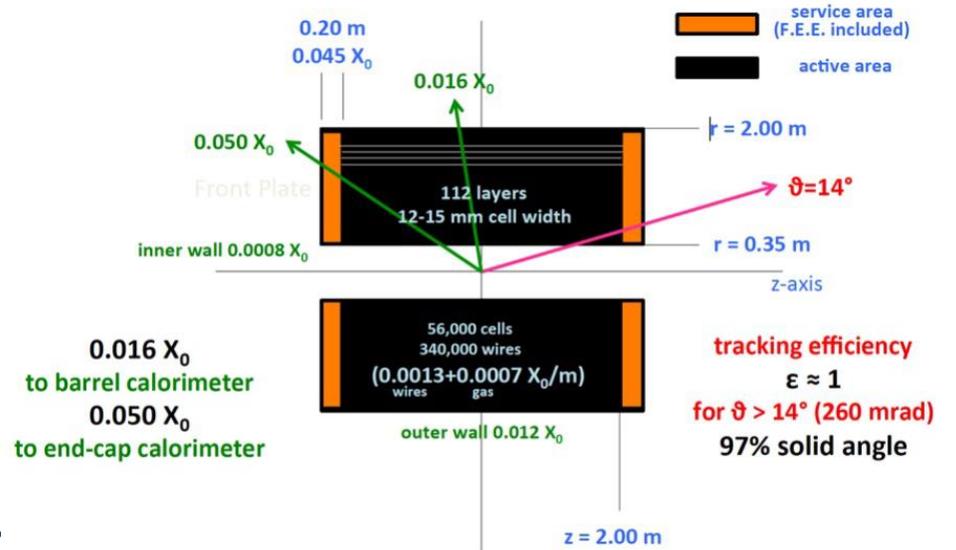

CEPC Design (2016)

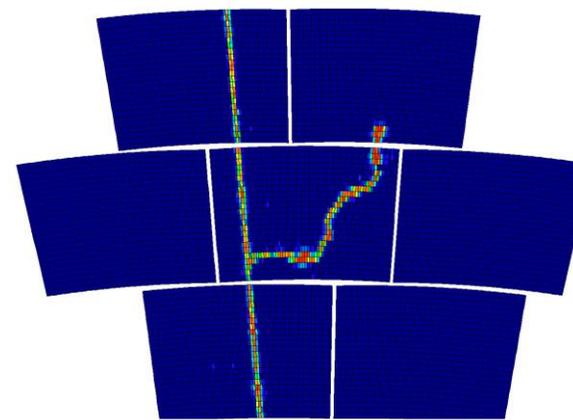

Slice test: 2-chip ladders in 6 double layers

- Long and small cell size drift chamber
  - 4 m wire length
  - >100 sampling on track
  - $\sigma_{R\phi} \sim 80 \mu\text{m}$ ,  $\sigma_z \sim 0.6 \text{ mm}$  (stereo)
- Increase wire tensile strength (C wires)
- Stress on mechanical structures
- Implement on-line pulse processing for cluster counting
  - improves position and dE/dx for particle ID

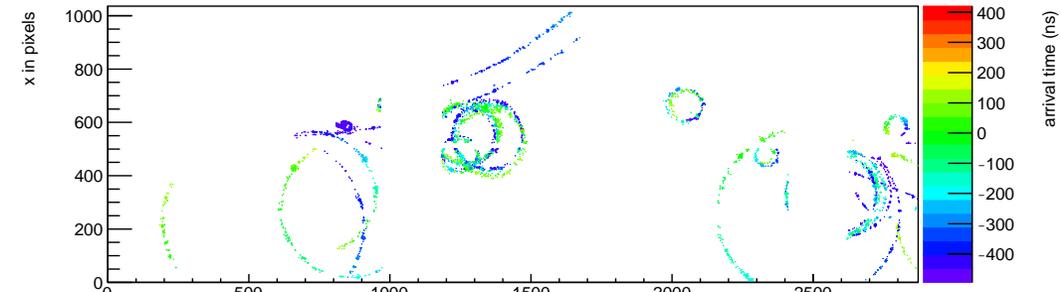

- Charge multiplication with GEM or Micromegas
  - ~100 measurements
  - $\sigma_{R\phi} \sim 100 \mu\text{m}$ ,  $\sigma_z \sim 0.3 \text{ mm}$
- Readout
  - **Pads:**  $O(\text{mm}^2)$  area: ~50-100 electrons each. PID by  $dE/dx$  (truncated mean charge)
  - **Digital TPC** (Si-pixels) : detect individual electrons with on  $O(50\mu)$  digital pixels. PID by  $dN/dx$  (cluster counting)
- Ion backflow
  - The possibility of gating exists only at ILC. For other colliders (continuous beam or high rate bunch crossings) gating is not possible.
  - There is a natural ion backflow suppression in Micromegas, but not sufficient at the Z pole.
  - R&D needed

P. Colas at *ECFA Topical workshop on tracking and vertexing 2023*

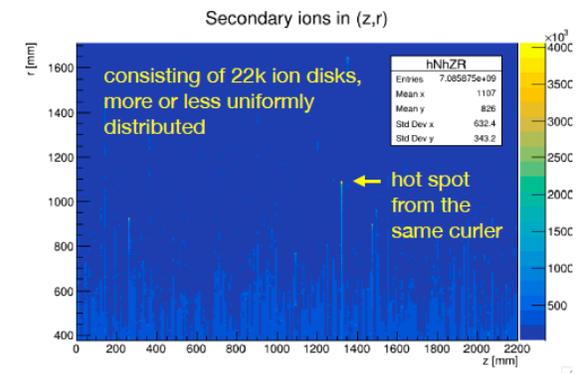

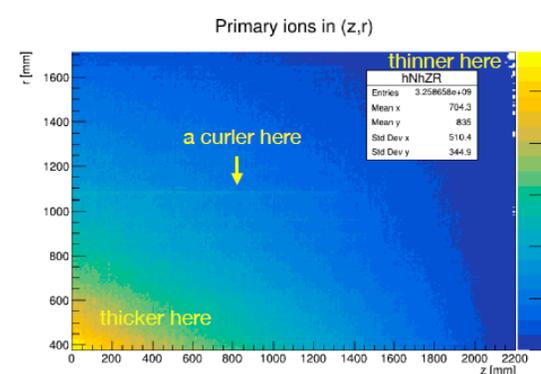

DESY LCTPC-Pixel Testbeam Run 6969 Event 2 Bfield 1.0 T beam momentum 6 GeV/c

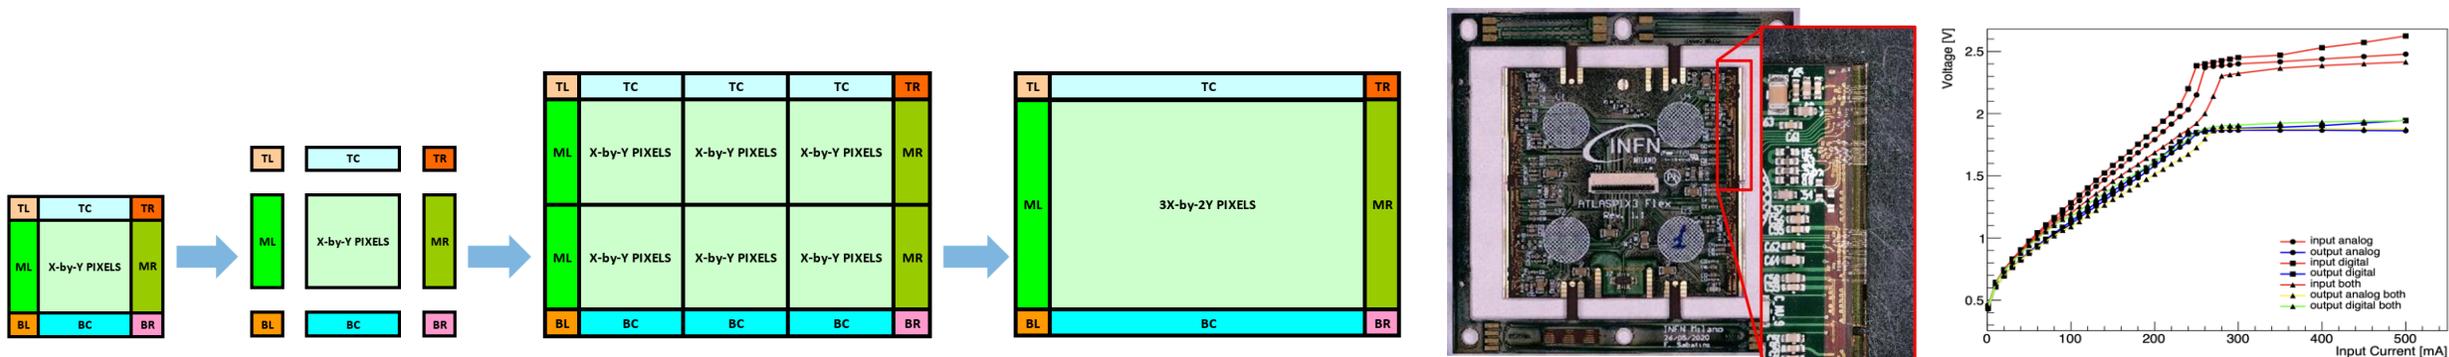

Primary Ions

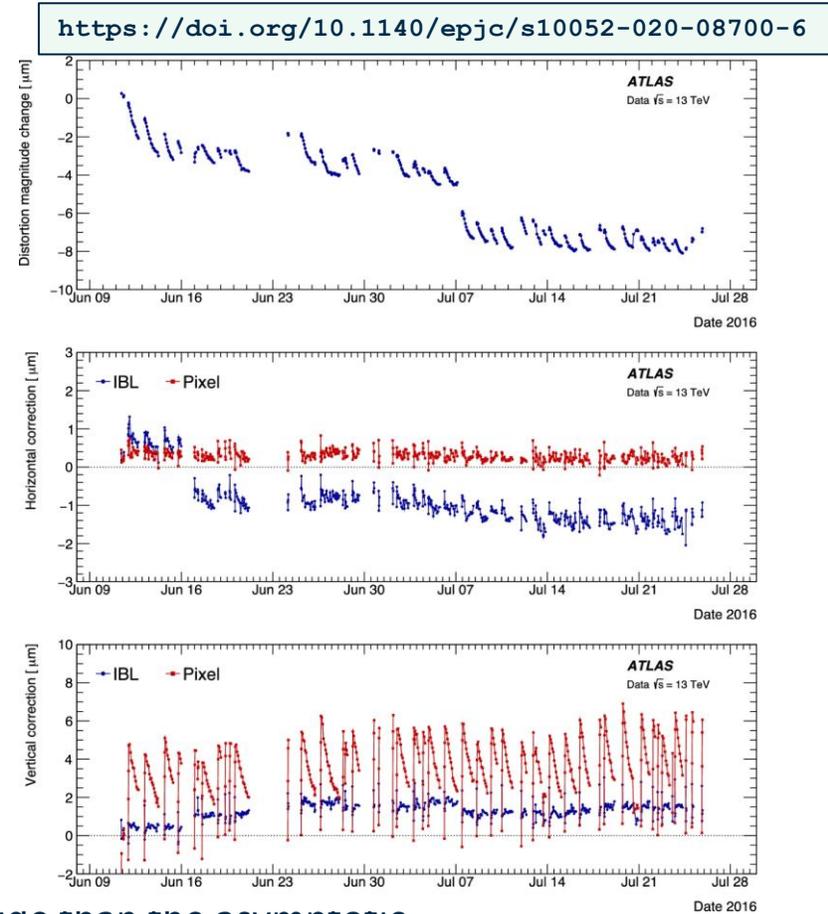

Ion Back Flow

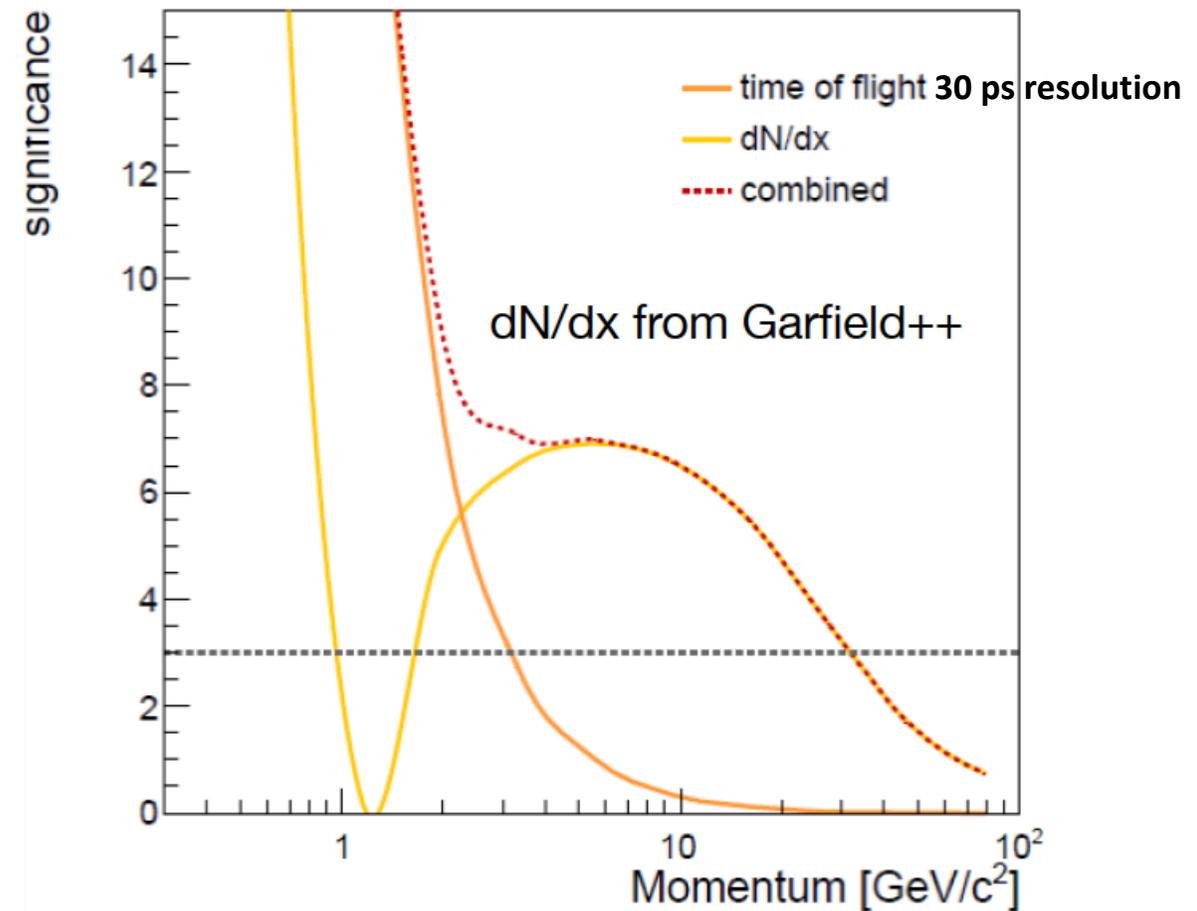

- Large silicon area to cover:  $\sim 100 \text{ m}^2$ 
  - Certainly Si-strips are able to sustain particle rates and radiation doses
  - But limited suppliers, even if passive CMOS strips are entering the game as an alternative procurement source
- **Depleted monolithic CMOS pixel detectors** are an option for large areas too
  - CMOS Foundries are able to produce large volume of detectors at a convenient price
  - Requirement on granularity and power consumption may be loose than for the vertex detector
  - Need at least time stamping of hits
  - To be practical need to aggregate multiple chips in larger units: **stitching**
  - Develop a power distribution scheme: **serial powering(?)** require HV capabilities, not available in all technologies

- For cross section measurements need to keep systematics on the angular acceptance at the level of  $50 \mu\text{rad}$  at  $\theta = 10^\circ$ .
- in principle, silicon is a very good ruler:
  - Inner Silicon Tracker disks: at 40 cm,  $\delta R_{\text{sys}} < 20 \mu\text{m}$ 
    - alignment in principle is better than that, but stability need to be followed accordingly
    - for example: in ATLAS seen few  $\mu\text{m}$  systematics movements, but the tracker support will be much lighter in IDEA
  - SiWrapper: at 2 m,  $\delta R_{\text{sys}} < 100 \mu\text{m}$ 
    - benefits from pixel structure (order of pixel size)
    - if anchored to the calorimeter provides an independent frame, giving some redundancy
- With  $50 \mu\text{m}$  pitch pixels and digital readout,  $\sigma_z = 14 \mu\text{m}$ , expect a  $\theta$  resolution below  $10 \mu\text{rad}$ 
  - with the caveat that multiple scattering effects can be of a similar order of magnitude than the asymptotic resolution even for  $Z \rightarrow \mu\mu$  events:  $1\% X_0$  is  $30 \mu\text{rad}$  for  $p=45 \text{ GeV}$  at  $90^\circ$
  - instabilities at the  $\mu\text{m}$  level may have an impact in the accuracy of the acollinearity measurement for beam angle crossing determination
  - having an independent detector with 2 m lever arm and same resolution as the inner tracker will allow the monitoring and correction of instabilities in both coordinates

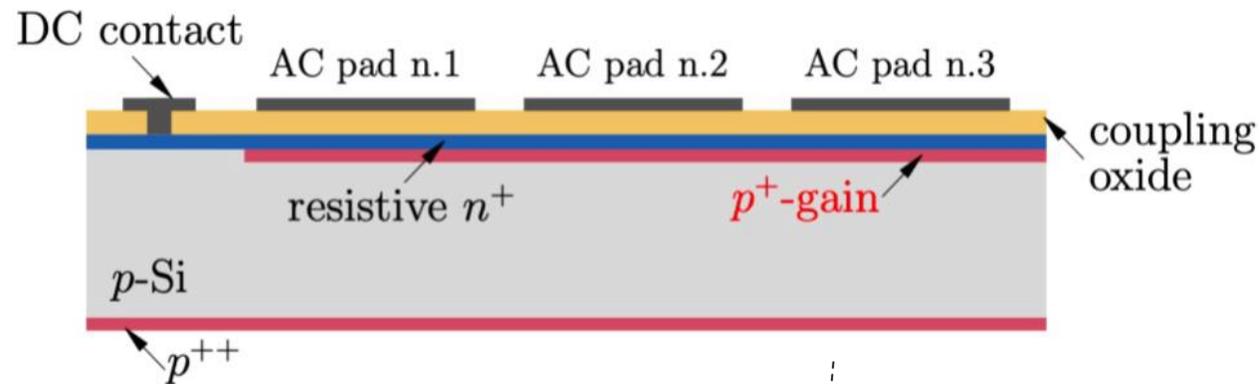

- **An interesting option** to investigate in the external tracker is to contribute to particle identification
- **dN/dx** measurements in Drift Chamber provides  $3\sigma$  separation up to 30 GeV/c
- Confusion region about 1 GeV/c can be covered by **TOF** measurement with resolution **<100 ps**
- **Can it be implemented in the Si Wrapper without compromising the spatial resolution?**

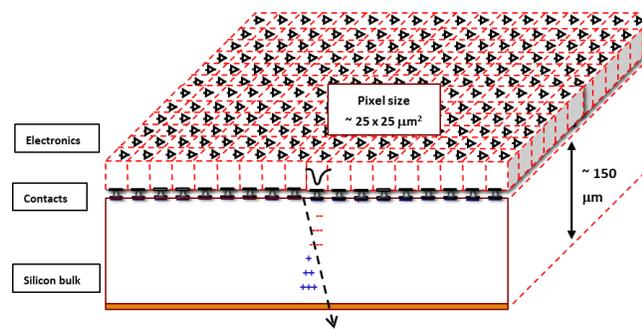

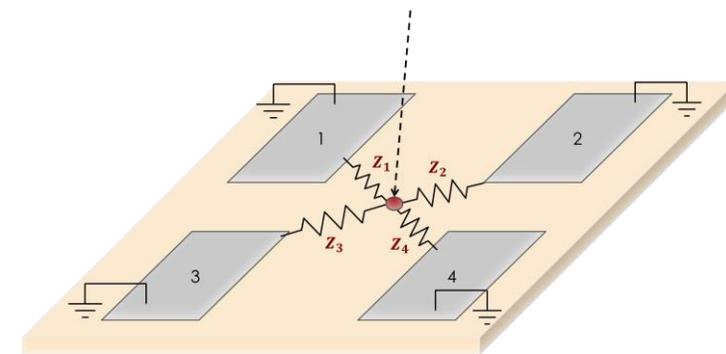

# Resistive Silicon Detectors (RSD)

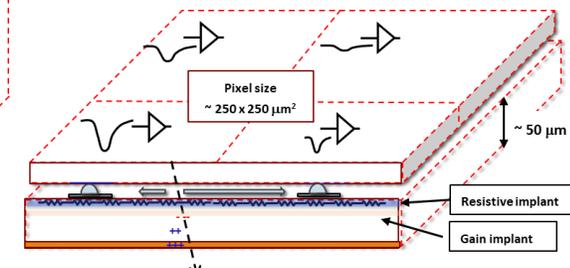

- LGAD detector with **continuous gain layer**
- Charge collection through **resistive n-layer**
- Readout by induction on **AC coupled pads**
- Fully active detector
  - avoids inefficient regions due to the insulation between pixels needed in LGAD sensors
- Charge sharing defined by the relative impedance of the path between the charge deposition and readout electrodes
  - pad pitch  $\gg$  lateral dimension of charge deposit
  - sharing is deterministic (in low pitch pixel detectors is dominated by Landau fluctuations)
  - resolution depends on the S/N ratio of the readout electronics

$$S_i = \frac{1/Z_i}{\sum 1/Z_i}$$

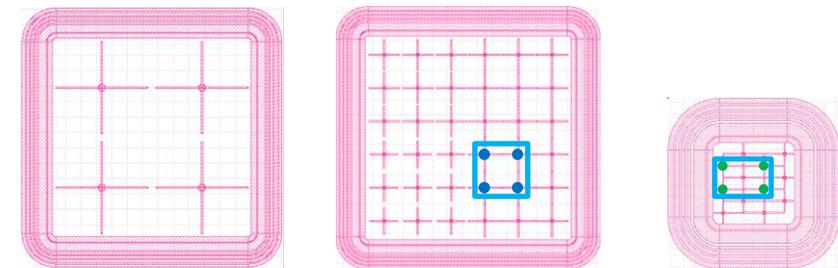

Standard Silicon Detector

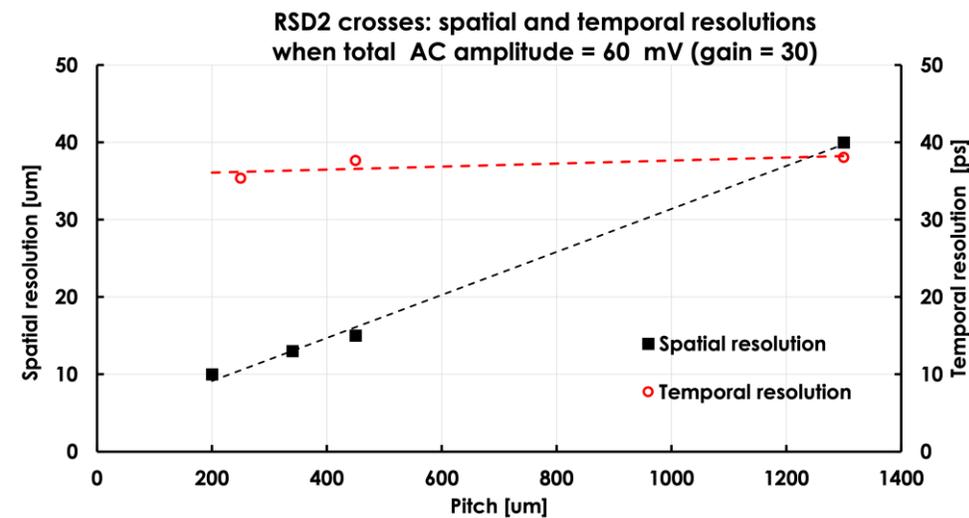

Resistive Read-out Detector

- Spatial resolution  $\ll$  pixel pitch
  - 10  $\mu\text{m}$  achieved in lab tests with 200  $\mu\text{m}$  pixel pitch
  - more space in readout pixel cell to implement precision TDC
- Timing resolution about independent from pixel pitch
- Drawbacks:
  - hybrid detector (but bump-bond pitch is easily achievable commercially)
  - effective pitch is  $>2$  readout pitch: particle flux limited by pixel size
- Suited for Si Wrapper:
  - particle density at 2 m from the interaction region should not be a concern for a  $e^+e^-$  colliders
  - no need to push for extremely low material: hybrid detector are acceptable

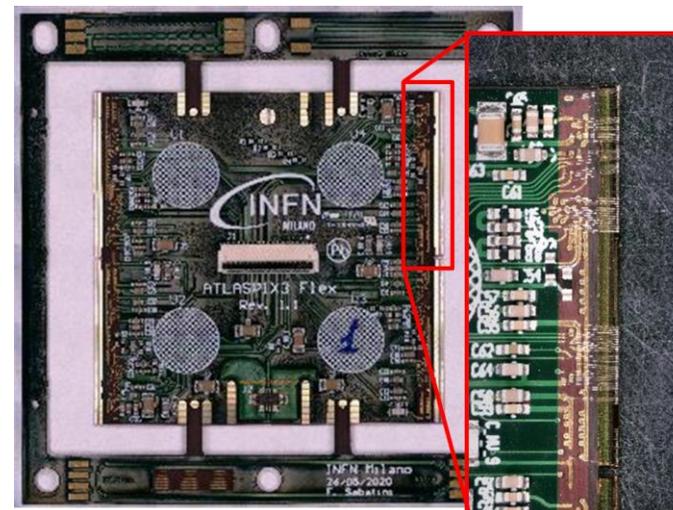

$1.3 \times 1.3 \text{ mm}^2$     $450 \times 450 \mu\text{m}^2$     $200 \times 340 \mu\text{m}^2$   
Cross-shaped electrodes

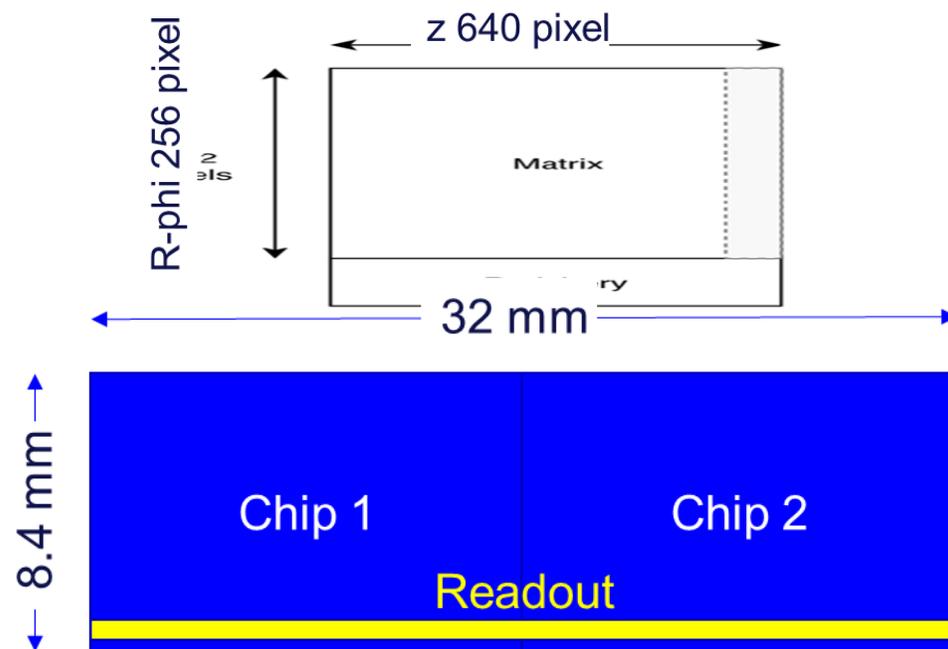

## Internal tracker

- **Multi-chip module assembly**
  - **ATLASPIX3**: full size TSI 180 nm sensor
  - aggregates electrical services and connection for multiple sensors
  - **quad module**, inspired by ITk pixels
  - building block for staves and disks
  - implement serial powering capabilities ( $175 \text{ mW/cm}^2$ )

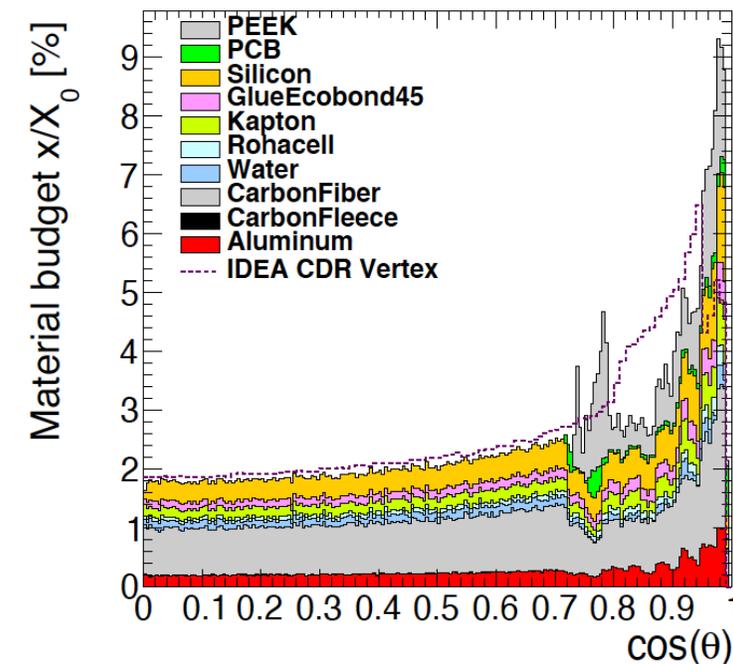

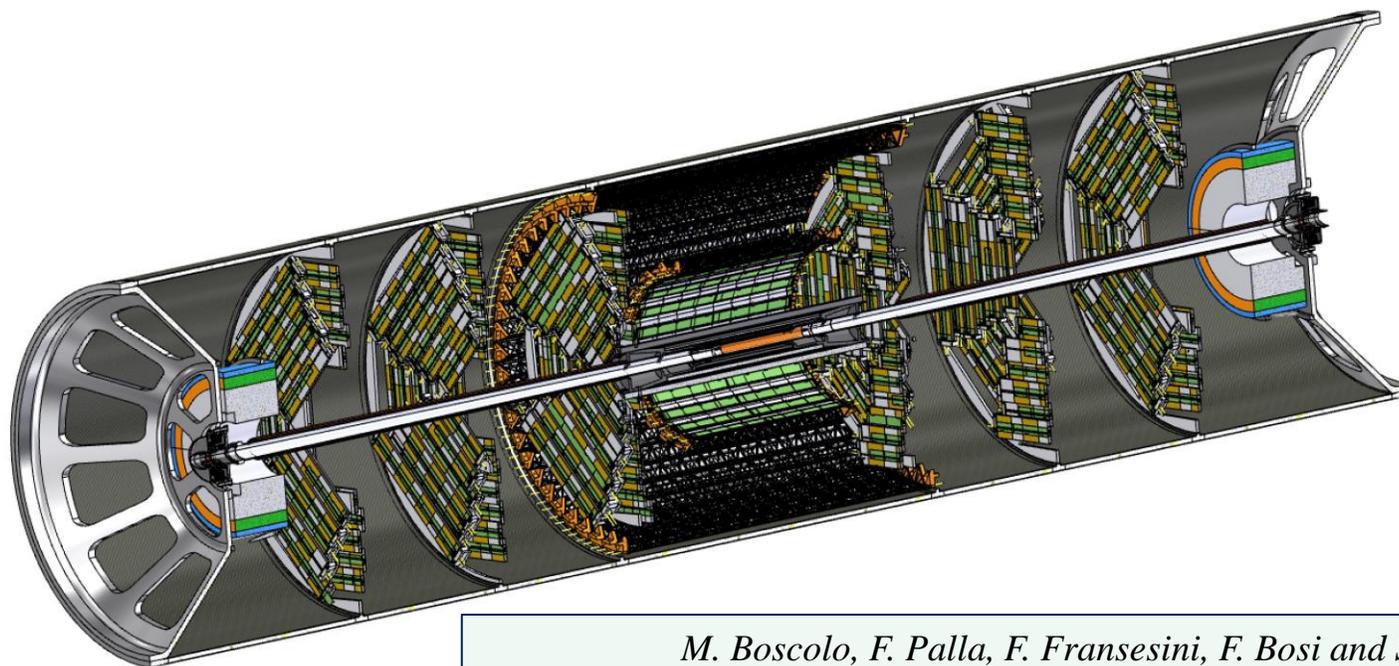

## Vertex detector

- **ARCADIA** inspired chip chain
  - Active area 640 pixel (16 mm) in z and 256 pixels (6.4 mm) in  $r-\phi$
  - Chip periphery plus an inactive zone: total of 2 mm in  $r-\phi$
  - Chips are side-abutable in z
  - Power budget: assume  $50 \text{ mW/cm}^2$  - including power and readout buses

- Development with the FCCee MDI accelerator group
- Integration with **realistic** local support, cooling and electrical services
- Mockup to be build at LNF to demonstrate the interface with the machine and the mixel cooling
  - air cooling for vertex
  - watercooling for internal tracker

*M. Boscolo, F. Palla, F. Franesini, F. Bosi and S. Lauciani, Mechanical model for the FCC-ee MDI, EPJ Techn Instrum* **10**, 16 (2023). <https://doi.org/10.1140/epjti/s40485-023-00103-7>

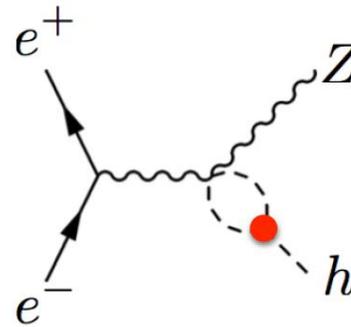

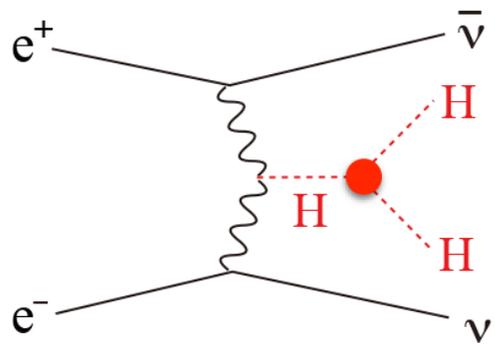

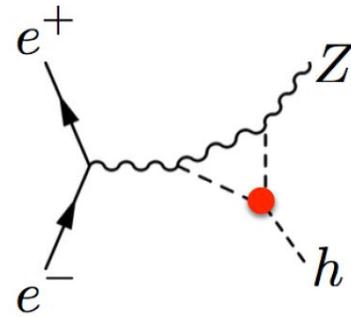

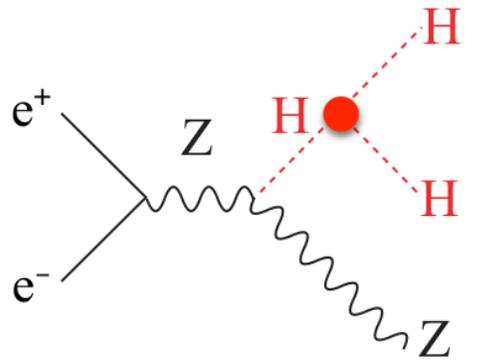

- Future Higgs factories are an important step in improving our understanding of QFT
  - Complementary to the HL-LHC physics program
  - Completing our understanding of the Higgs sector
  - Extending the program to lower energies (EW and flavour physics) and to higher energies (top mass and Higgs trilinear coupling)
- There are stimulating technical challenges to face:
  - Can we have a vertex with  $<25 \mu\text{m}$  pitch, time stamping at 30 ns and  $10 \text{ mW/cm}^2$  power?
  - Can we build a fully pixelated tracker (stitching, serial powering, technology node...)?
  - How do we perform PID in an effective way (cluster counting, TOF, cherenkov...)?
- Timeline is not closed yet: expect to start detector construction between early '30s and mid '40s
  - The technologies we are developing now are likely not the ones we will use then!
  - Nevertheless, building realistic prototypes with what is available now will allow to focus on some critical system issues:
    - **understand and improve**, instead of dreaming on paper and face reality reality later

All future colliders combined with HL-LHC

- **Complete system consists of 900'000 cm<sup>2</sup> area / 4 cm<sup>2</sup> chip = 225k chips (56k quad-modules)**
  - aggregation of several modules for data and services distribution is essential
  - inner tracker will be 5--10% of this
- **Data rate** constrained by the inner tracker
  - average rate  $10^{-4}$  -  $10^{-3}$  particles cm<sup>-2</sup> event<sup>-1</sup> at Z peak
  - assuming 2 hits/particle, 96 bits/hit for ATLASPIX3
  - **640 Mbps link/module** (assuming local module aggregation) provides ample operational margin
  - 16 modules can be arranged into **10 Gbps fast links: 3.5k links**
    - can also assume 100 Gbps links will be available: **350 links**
- **DAQ architecture**
  - **triggerless readout** will fit the data transmission budget but requires off-chip re-ordering of data
  - **triggered readout** will be **simpler** and would also reduce the bandwidth occupancy
- **Power consumption**
  - ATLASPIX3 power consumption **150 mW/cm<sup>2</sup>**
  - 600 mW/chip → 2.4 W/module → **total FE power 130 kW**
  - additional power for on detector aggregation and de-randomizations **~2W/link**

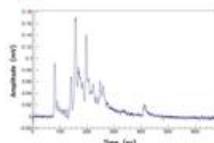

## 4<sup>th</sup> CHALLENGE: data reduction

The excellent performance of the **cluster finding** algorithms in offline analysis, relies on the assumption of being able to transfer the full spectrum of the digitized drift signals.

However ...

according to the **IDEA drift chamber operating conditions**:

- 56448 drift cells in 112 layers (~130 hits/track)
- maximum drift time of 500 ns
- cluster density of 20 clusters/cm
- signal digitization 12 bits at 2 Gsa/s

... and to the **FCC-ee running conditions at the Z-pole**

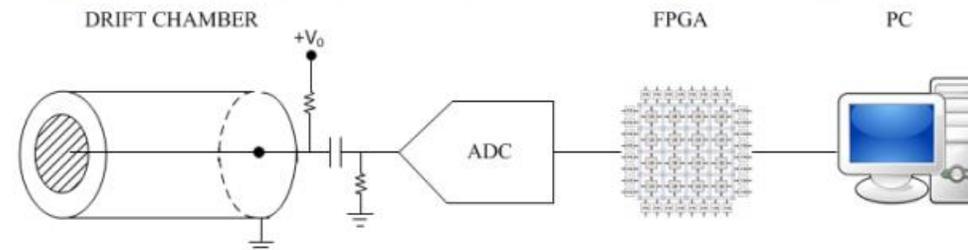

- 100 KHz of Z decays with 20 charged tracks/event multiplicity
- 30 KHz of  $\gamma\gamma \rightarrow$  hadrons with 10 charged tracks/event multiplicity
- 2.5% occupancy due to beam noise
- 2.5% occupancy due to hits with isolated peaks

Reading both ends of the wires,  $\Rightarrow$  **data rate  $\geq 1$  TB/s !**

**Solution** consists in transferring, for each hit drift cell, instead of the **full signal spectrum**, only the **minimal information** relevant to the application of the **cluster timing/counting techniques**, i.e.:

**the amplitude and the arrival time** of each peak associated with each individual ionisation electron.

This can be accomplished by using a **FPGA** for the **real time analysis** of the data generated by the drift chamber and successively digitized by an ADC.

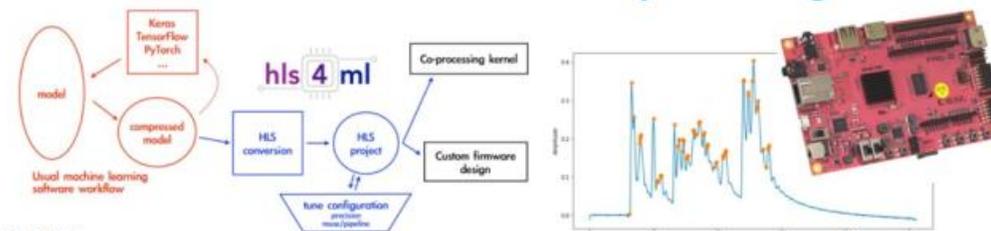

**Single channel** solution has been successfully verified.

G. Chiarello et al., *The Use of FPGA in Drift Chambers for High Energy Physics Experiments* May 31, 2017  
DOI: [10.5772/66853](https://doi.org/10.5772/66853)

With this procedure **data transfer rate is reduced to ~ 25 GB/s**. Extension to a 4-channel board is in progress. Ultimate goal is a multi-ch. board (128 or 256 channels) to **reduce cost** and complexity of the system and to gain flexibility in determining the **proximity correlations** between hit cells for track **segment finding** and for **triggering** purposes.

**Implementing ML algorithms on FPGA for peak finding**

F. Grancagnolo - ECFA WG2

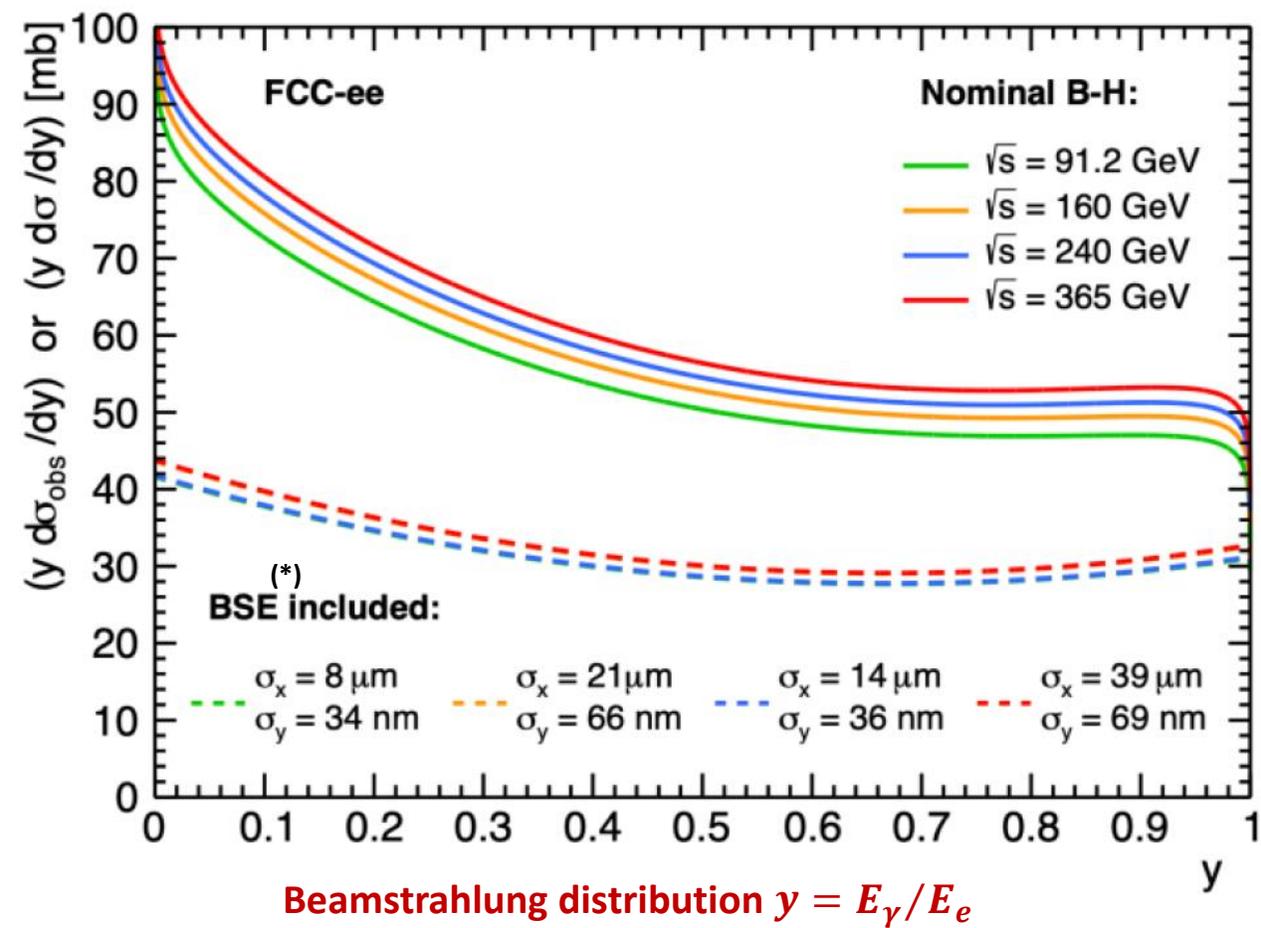

F. Grancagnolo at ECFA Topical workshop on tracking and vertexing 2023

- Version ATLASPIX3.1 can be biased by serial powering through two shunt/low dropout regulators
  - digital and analog (VDDD/A)
  - 3 bits to tune threshold of shunt regulator
  - 3 bits to tune VDD
- Measured regulator performance
  - threshold and noise performance are the same using SLDO or direct VDDD/A powering
  - DAC dynamic range of few tens of mV
  - Full chip turn-on at  $I=300$  mA
  - Input voltage 2.3 V
  - Power consumption:  $\sim 700$  mW/chip or  $\sim 175$  mW/cm<sup>2</sup>
- Integration model is to join modules by a bus implementing a serial powering chain
  - examples in F. Palla's talk
  - metal in the module hybrid and the power bus dominates the thickness of a detector layer ( $\sim 0.44\% X_0$ )
  - considering to move Al as conductor for PCBs

## FCC-ee: SR Photon Spectra

(\*) Beam size effects

- Circulated drafts of the DRD3 and DRD7 proposals
- Monolithic CMOS developments are shared between DRD3.1 (sensor development) and DRD7.6 (large systems)
  - TSI180 is within the technologies considered in DRD3.1
  - the LF110nm ARCADIA platform is one of the two technologies included in DRD7.6 together with TowerJazz 65nm
- Developments on power distribution are the subject of a DRD7.1 process
  - SLDO has not been much investigated for Monolithic CMOS detector (depends on HV capabilities)
- LGAD in RSD technology are considered for two research goals in DRD3.2

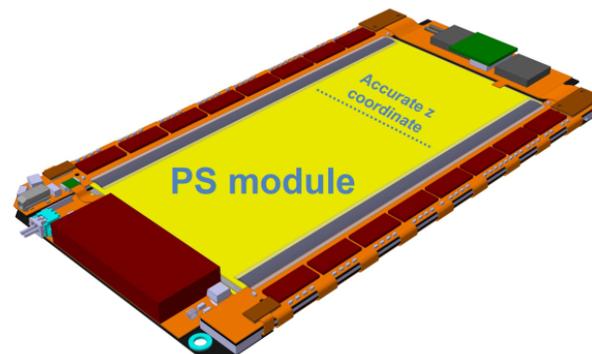

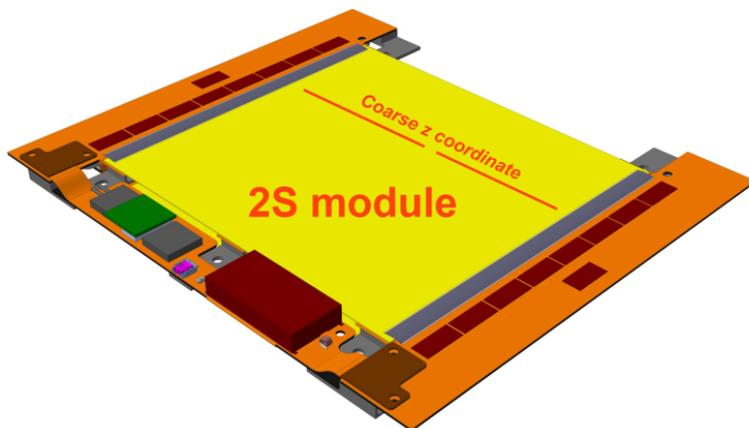

- **RG 2.3: LGAD Sensors with very high fill factor, and an excellent spatial and temporal resolution.**
  - 2024-2025: LGAD test structures of different technologies (TI-LGAD, iL-GAD, RSD, DJ-LGAD), matching existing read-out ASICs.
- **RG 2.4: LGAD sensors for Time of Flight applications**
  - 2024-2026: Production of LGAD (RSD) sensors with large size for Tracking/Time of Flight applications to demonstrate yield and doping homogeneity. Study of spatial and temporal resolutions as a function of the pixel size.
  - 2026-2028: Structures produced with vendors capable of large-area productions to demonstrate the industrialization of the process.

Project 7.6.a	7.1.b
Common access to selected imaging technologies and IP blocks	Powering Next Generation Detector Systems
The successful deployment of monolithic sensors in the community demonstrates their enormous potential. Efficient and affordable access to these technologies and IP-blocks requires concentration of resources	Improve power efficiency of detector systems at reduced material budget while meeting ultra-high TID tolerance. Improve efficiency of serially powered systems using switching mode shunt elements.
The main deliverables are: the shared PDKs, the chips resulting from the submissions and their test results. Supported technologies are: Tower Jazz 180nm, TPSCo 65nm, LFoundry 110nm.	-GaN DC-DC Converter: conversion factor 10, 10A, 1MHz, efficiency 95%, -Resonant Converter: conversion factor 5, 500mA, 30MHz, efficiency 75 %, -3-level Buck Converter: conversion factor 5-2, 500mA, 30MHz, efficiency 75 % -Capless-LDO: 1.1-1.2Vin, 0.9Vout, 200mA -GaN DC-DC Current Source: 48/24Vin, 10A, 200W, 2 MHz -SLDO: 1.4-2Vin, 0.9-1.2Vout, 1A Iload, 1A Ishunt
CMOS sensors are considered for several types of detectors: calorimeters, trackers, etc. They require specific expertise in analog and digital IC design, device design and technology, and significant testing effort. The project is therefore transversal and multi-disciplinary.	Joint effort in power electronics, ASIC and PCB design, thermal management, EMC, reliability. Necessary for all particle detector systems.
