## Study of the neutron rich nuclei via heavy-ion double charge exchange reaction

*Tuesday, 27 March 2012 10:15 (20 minutes)*

We are proposing a new powerful probe of heavy-ion double charge exchange (HIDCX) reaction, the  $(^{18}\text{O}, ^{18}\text{Ne})$  reaction, for the study of neutron rich nuclei. Ground states of  $^{18}\text{O}$  and  $^{18}\text{Ne}$  are among the same supermultiplet and the transition between them is just double spin-isospin flips keeping the spatial wavefunction unchanged. One can expect the transition is simple and its transition amplitude is large.

As a first step to establish the HIDCX reaction,  $^{12}\text{Be}$  and  $^9\text{He}$  nuclei were studied via the  $^{12}\text{C}(^{18}\text{O}, ^{18}\text{Ne})^{12}\text{Be}$  and  $^9\text{Be}(^{18}\text{O}, ^{18}\text{Ne})^9\text{He}$  reactions at 80 MeV/nucleon. The nucleus  $^{12}\text{Be}$  is one of the symbolic nucleus evidencing disappearance of  $N=8$  magicity. Spin-parities for low-lying states in  $^{12}\text{Be}$  are well understood. The nucleus  $^9\text{He}$  is, however, unbound and its spin-parities have not certainly been determined. Thus, by making use of shape of angular distribution of the differential cross section in  $^{12}\text{Be}$ , we may make a new assignment of spin-parities in  $^9\text{He}$ .

We performed the HIDCX experiment at the RCNP, Osaka University. The high resolution spectrometer Grand Raiden provide us to detect  $^{18}\text{Ne}$  particles which were well isolated from other isotopes. This is due to its unique  $A/Q$  value of 9/5. In the  $^{12}\text{Be}$  spectrum, three peaks were observed and show different angular distribution shapes, indicating different spin-parities. In the  $^9\text{He}$  spectrum, however, we did not observe any peaks. In the presentation, I will report the detail of the experiment and the result.
