30.07.2024

## Rare radiative leptonic decays $B_{s(d)} \rightarrow \gamma l^+ l^-$

- Induced by the weak flavor-changing neutral currents (FCNC)  $b \rightarrow s(d)$
- Forbidden at the tree level of SM  $\Rightarrow$  occur only via the diagrams with loops  
New particles might contribute to the loops  $\Rightarrow$  potential New Physics
- Small branchings of the order of  $10^{-8} \div 10^{-10}$  are predicted in SM
- Searched for with the same signature as  $B_{s(d)} \rightarrow l^+ l^-$ , i.e. without reconstructing a photon. Currently, from [LHCb (2022)], [LHCb (2022)] the upper limit is at

$$\text{Br}(B_s^0 \rightarrow \gamma \mu^+ \mu^-) < 2.0 \cdot 10^{-9} \quad [m_{\mu\mu} > 4.9 \text{ GeV}]$$

- Analogously to  $B_s \rightarrow \{K^{(*)}, \phi\} l^+ l^-$ , can be tested for the Lepton Flavor Violation  
See discussion in [D. Guadagnoli, M. Reboud and R. Zwicky (2017)].
- Theoretically,  $B_{s(d)} \rightarrow \gamma\gamma$  decay has the same topology but its branching is enhanced by the factor  $1/\alpha$ . Currently, from [Belle (2015)] the upper limit is  $\text{Br}(B_s^0 \rightarrow \gamma\gamma) < 3.1 \cdot 10^{-6}$

Pic.: Differential branching fractions for  $B_s \rightarrow \gamma l^+ l^-$  (left) and  $B_d \rightarrow \gamma l^+ l^-$  (right) decays. The figures are taken from [A. Kozachuk, D. Melikhov and N. Nikitin (2018)].

# FCNC $b \rightarrow s(d) \gamma$ and $b \rightarrow s(d) l^+ l^-$ transitions in SM

- The dominant contribution to  $b \rightarrow s \gamma$  amplitude comes from a penguin with top quark. At scale  $\mu \sim m_b$  the heavy degrees of freedom ( $t$ -quark,  $W$ -boson) are integrated out, thus leading to the local operator  $\mathcal{O}_7$

$$H_{\text{top}}^{(b \rightarrow s \gamma)} = -\frac{G_F}{\sqrt{2}} V_{tb} V_{ts}^* \frac{e}{8\pi^2} C_7(\mu) \mathcal{O}_{7\gamma},$$

$$\mathcal{O}_{7\gamma} = \bar{s} \sigma_{\mu\nu} (1 + \gamma_5) b \cdot F^{\mu\nu}$$

- The top-quark contribution to  $b \rightarrow s l^+ l^-$  amplitude is generated not only by the electromagnetic penguin operator  $\mathcal{O}_{7\gamma}$ , but also by the operators  $\mathcal{O}_{9V}$  and  $\mathcal{O}_{10A}$  described by the box (a) and penguin (b) diagrams

$$H_{\text{top}}^{(b \rightarrow s ll)} = \frac{G_F}{\sqrt{2}} \frac{e^2}{8\pi^2} V_{tb} V_{ts}^* [$$

$$- 2im_b \frac{C_7(\mu)}{q^2} \bar{s} \sigma_{\mu\nu} q^\nu (1 + \gamma_5) b \cdot \bar{l} \gamma^\mu l +$$

$$C_{9V}(\mu) \mathcal{O}_{9V} + C_{10A}(\mu) \mathcal{O}_{10A}]$$

- The subleading contribution to  $b \rightarrow s \gamma$  and  $b \rightarrow s l^+ l^-$  amplitudes comes from a charm-quark loop. The four-fermion interaction is described by the linear combination of  $\mathcal{O}_1$  and  $\mathcal{O}_2$  local operators, that can be rearranged into the color singlet-singlet and octet-octet operators

$$H_{\text{eff}}^{(b \rightarrow s \bar{c} c)} = H_{\text{fact charm}}^{[1 \times 1]} + H_{\text{nf charm}}^{[8 \times 8]}$$

$$\left\{ \begin{array}{l} H_{\text{fact charm}}^{[1 \times 1]} = -\frac{G_F}{\sqrt{2}} V_{cb} V_{cs}^* \left( C_1 + \frac{C_2}{3} \right) 4 \bar{s}_L \gamma_\mu b_L \cdot \bar{c}_L \gamma_\mu c_L \\ H_{\text{nf charm}}^{[8 \times 8]} = -\frac{G_F}{\sqrt{2}} V_{cb} V_{cs}^* (2C_2) 4 \bar{s}_L \gamma_\mu t^a b_L \cdot \bar{c}_L \gamma_\mu t^a c_L \end{array} \right.$$

# Top and charm contributions to $\bar{B}_s \rightarrow \gamma l^+ l^-$ amplitude

**Pic.:** Diagrams describing the top-quark contributions. Dashed circle denotes the  $O_7$  operator, solid circle —  $O_9$  operator. In diagrams (a) and (b) the real photon is emitted by spectator  $s$ -quark; in diagram (c) the real photon is emitted by spectator  $b$ -quark. We do not show  $1/m_b$ -suppressed diagrams where real or virtual photon is emitted by spectator  $b$ -quark.

**Pic.:** Diagrams describing the charm-quark contributions: (a) and (b) — Nonfactorizable contributions induced by the  $[8 \times 8]$  part of the Hamiltonian (solid squares), (c) Factorizable contribution induced by the  $[1 \times 1]$  part of the Hamiltonian (empty squares); a similar factorizable contribution with the real photon emitted from the charm-quark loop vanishes and is not shown.

# Nonfactorizable charm

$$\mathcal{A}_{\text{nf charm}}^{(\bar{B}_s \rightarrow \gamma\gamma)} = \left\{ H_{\rho\eta}(q, q') \varepsilon_\rho(q) \varepsilon_\eta(q') + H_{\rho\eta}(q', q) \varepsilon_\rho(q') \varepsilon_\eta(q) \right\}$$

$$\mathcal{A}_{\text{nf charm}}^{(\bar{B}_s \rightarrow \gamma ll)} = \frac{e}{Q^2} \left\{ H_{\rho\eta}(q, q') \bar{l} \gamma_\rho l \varepsilon_\eta(q') + H_{\rho\eta}(q', q) \varepsilon_\rho(q') \bar{l} \gamma_\eta l \right\}$$

Since the top-quark and the charm-quark amplitudes,

$$\mathcal{A}_{\text{top}}^{(\bar{B}_s \rightarrow \gamma\gamma)}, \mathcal{A}_{\text{top}}^{(\bar{B}_s \rightarrow \gamma ll)}, \mathcal{A}_{\text{nf charm}}^{(\bar{B}_s \rightarrow \gamma\gamma)}, \mathcal{A}_{\text{nf charm}}^{(\bar{B}_s \rightarrow \gamma ll)},$$

have the similar structure, it is convenient to describe the effect of charm as a (non-universal) addition to the Wilson coefficient  $C_7$ ,

$$C_7^{\text{eff}} = C_7 + \Delta_{V(A)}^{\text{NF}} C_7.$$

- $H_{\rho\eta}$  tensor in a  $T$ -product form:

$$H_{\rho\eta}(q', q) = i \int dz e^{iq'z} \langle 0 | T \{ \bar{e} Q_c c(z) \gamma_\rho c(z), i \int dy L_{\text{weak}}^{b \rightarrow s \bar{c} c [8 \times 8]}(y), i \int dx L_{\text{GCC}}(x), e Q_s \bar{s}(0) \gamma_\eta s(0) \} | \bar{B}_s(p) \rangle$$

- Derived expression for the  $H_{\rho\eta}$  tensor in Standard Model:

$$H_{\rho\eta}(q', q) = -\frac{G_F}{\sqrt{2}} V_{cb} V_{cs}^* e^2 (2C_2) Q_s Q_c \times \frac{1}{(2\pi)^8} \int dk dy e^{-i(k-q')y} dx d\kappa e^{-i\kappa x}$$

$$\Gamma_{cc}^{\mu\nu\rho(ab)}(\kappa, q) \langle 0 | \bar{s}(y) \gamma^\eta \frac{\not{k} + m_s}{m_s^2 - k^2} \gamma^\mu (1 - \gamma^5) t^a B_\nu^b(x) b(0) | \bar{B}_s(p) \rangle.$$

- In the case of at least one real photon ( $q'^2 = 0$  or  $q^2 = 0$ ),  $H_{\rho\eta}$  contains only 2 form factors  $\mathcal{H}_{V,A}^{\text{NF}}(q^2, q'^2)$ ,

$$H_{\rho\eta}(q', q) = -\frac{G_F}{\sqrt{2}} V_{cb} V_{cs}^* e^2 (2C_2) Q_s Q_c \left[ \varepsilon_{\rho\eta q'q} \mathcal{H}_V^{\text{NF}} - i \mathcal{H}_A^{\text{NF}} (g_{\eta\rho} q q' - q'_\eta q_\rho) \right].$$

Pic.: One of the diagrams describing charm loop contribution to  $B_s \rightarrow \gamma\gamma^{(*)}$  decay via nonfactorizable soft gluon exchange.

- Two one-loop diagrams with the  $\langle VVA \rangle$  structure give equal contributions to the three-point function  $\Gamma_{cc}^{\mu\nu\rho(ab)}$ .

- $\Gamma_{cc}^{\mu\nu\rho(ab)}$  can be parametrized with three form factors  $F_{0,1,2}(\kappa, q)$ . This representation works in the region of the external momenta far below the thresholds,  $q^2, \kappa^2, (\kappa + q)^2 \ll 4m_c^2$ .

Pic.: The  $\langle VVA \rangle$  triangle one-loop diagrams for  $\Gamma_{cc}^{\mu\nu\rho(ab)}$ .

For the parametrization

$$\Gamma_{cc}^{\mu\nu\rho}(\kappa, q) = -i(\kappa^\mu + q^\mu) \epsilon^{\nu\rho\kappa q} F_0 - i(q^2 \epsilon^{\mu\nu\rho\kappa} - q^\rho \epsilon^{\mu\nu q\kappa}) F_1 - i(\kappa^2 \epsilon^{\mu\rho\nu q} - \kappa^\nu \epsilon^{\mu\rho\kappa q}) F_2$$

the convolution with the gluon field  $B_\nu(x)$  might be fully given in terms of the gluon field strength  $G_{\nu\alpha}(x)$ ,

$$\int d\kappa e^{-i\kappa x} \Gamma_{cc}^{\mu\nu\rho(ab)}(\kappa, q) B_\nu^b(x) dx = \frac{1}{4} \int d\kappa e^{-i\kappa x} \bar{\Gamma}_{cc}^{\mu\nu\rho\alpha}(\kappa, q) G_{\nu\alpha}^a(x) dx,$$

and therefore **no explicit use of any specific gauge for the gluon field is necessary.**

$$\bar{\Gamma}_{cc}^{\mu\nu\rho\alpha}(\kappa, q) = (\kappa^\mu + q^\mu) \epsilon^{\nu\rho\alpha q} F_0 + (q^\rho \epsilon^{\mu\nu\alpha q} + q^2 \epsilon^{\mu\nu\rho\alpha}) F_1 + (\kappa^\mu \epsilon^{\alpha\nu\rho q} + \kappa^\rho \epsilon^{\alpha\mu\nu q} - \kappa q \epsilon^{\alpha\mu\nu\rho}) F_2,$$

where the form factors  $F_{0,1,2}$  are functions of three independent invariant variables  $q^2$ ,  $\kappa^2$ , and  $\kappa q$ :

$$F_i(\kappa^2, \kappa q, q^2) = \frac{1}{\pi^2} \int_0^1 d\xi \int_0^{1-\xi} d\eta \frac{\Delta_i(\xi, \eta)}{m_c^2 - 2\xi\eta\kappa q - \xi(1-\xi)q^2 - \eta(1-\eta)\kappa^2}, \quad i = 0, 1, 2,$$

$$\Delta_0 = -\xi\eta, \quad \Delta_1 = \xi(1-\eta-\xi), \quad \Delta_2 = \eta(1-\eta-\xi).$$

## Double collinear LC configuration

- In the HQ limit the double collinear kinematics dominates the NF charm-loop contribution to FCNC  $B$ -decay amplitudes.
- Applied for the calculation of NF charm-loop form factors in  $B_s \rightarrow \gamma\gamma$  decay. It was shown that the leading contribution is proportional to the following combination of the 3DAs:

$$\Psi_A + \Psi_V + 2(W + Y_A - \tilde{Y}_A) \sim (\lambda_E^2 + \lambda_H^2).$$

[Q. Qin, Y.-L. Shen, C. Wang and Y.-M. Wang (2023)]

$$\begin{aligned} x_\mu &\sim \bar{n}_\mu \text{ [gluon coordinate]}, \\ y_\mu &\sim n_\mu \text{ [light quark coordinate]}, \\ n^2 = \bar{n}^2 &= 0 \text{ and } n\bar{n} = 2, \\ v_\mu = p_\mu/M_B &= \frac{1}{2}(n_\mu + \bar{n}_\mu). \end{aligned}$$

The  $B$ -meson three-particle BS amplitude is parametrized by

$$\begin{aligned} \langle 0 | \bar{s}(\tau_1 n) G_{\nu\alpha}(\tau_2 \bar{n}) \Gamma b(0) | \bar{B}_s(p) \rangle &= \frac{f_B M_B^3}{4} \int D(\omega, \lambda) e^{-i(\lambda\tau_1 + \omega\tau_2)M} \text{Tr} \left\{ \gamma_5 \Gamma(1 + \not{p}) \right. \\ &\times \left[ (v_\nu \gamma_\alpha - v_\alpha \gamma_\nu) [\Psi_A - \Psi_V] - i\sigma_{\nu\alpha} \Psi_V + (n_\nu \gamma_\alpha - n_\alpha \gamma_\nu) (Y_A + W) + i\epsilon_{\nu\alpha\mu\beta} n^\mu \gamma^\beta \gamma^5 \tilde{Y}_A \right. \\ &\left. \left. + (\bar{n}_\nu \gamma_\alpha - \bar{n}_\alpha \gamma_\nu) (Y_A + W) + i\epsilon_{\nu\alpha\mu\beta} \bar{n}^\mu \gamma^\beta \gamma^5 \tilde{Y}_A + \dots \right] \right\}, \end{aligned}$$

where  $D(\omega, \lambda) = d\omega d\lambda \theta(\omega)\theta(\lambda)\theta(1 - \omega - \lambda)$ .

# Collinear LC configuration

- The amplitude differs by terms  $\mathcal{O}(\lambda_{B_s}/M_B)$  from the amplitude in the double-collinear approximation.
- Applied for calculation of NF charm-loop form factors in  $B \rightarrow K^{(*)}l^+l^-$ ,  $B \rightarrow K^*\gamma$  and  $B_s \rightarrow \phi l^+l^-$  decays.

[A. Khodjamirian, T. Mannel and N. Offen (2007)]

[A. Khodjamirian, T. Mannel, A. Pivovarov and Y.-M. Wang (2010)]

[N. Gubernari, D. van Dyk and J. Virto (2020)]

- $\{\Psi_A, \Psi_V\}$  + six 3DAs  $\{X_A, Y_A, \tilde{X}_A, \tilde{Y}_A, W, Z\}$  parametrizing the kinematics-dependent part.

$$x^2 = y^2 = 0 \text{ and } x \sim y$$

$$x = uy \text{ with } u \neq 0 \implies xy = 0$$

$$\begin{aligned} \langle 0 | \bar{s}(y) G_{\nu\alpha}(uy) \Gamma b(0) | \bar{B}_s(p) \rangle &= \frac{f_B M_B^3}{4} \int D(\omega, \lambda) e^{-i\lambda yp - i\omega u yp} \text{Tr} \left\{ \gamma_5 \Gamma(1 + \not{p}) \right. \\ &\times \left[ (p_\nu \gamma_\alpha - p_\alpha \gamma_\nu) \frac{1}{M_B} [\Psi_A - \Psi_V] - i\sigma_{\nu\alpha} \Psi_V - \frac{(y_\nu p_\alpha - y_\alpha p_\nu)}{yp} \left( X_A + \frac{\not{y}}{yp} M_B W \right) \right. \\ &\left. \left. + \frac{(y_\nu \gamma_\alpha - y_\alpha \gamma_\nu)}{yp} M_B \left( Y_A + W + \frac{\not{y}}{yp} M_B Z \right) - i\epsilon_{\nu\alpha\mu\beta} \frac{y^\mu p^\beta}{yp} \gamma^5 \tilde{X}_A + i\epsilon_{\nu\alpha\mu\beta} \frac{y^\mu \gamma^\beta}{yp} \gamma^5 M_B \tilde{Y}_A \right] \right\}, \end{aligned}$$

where the continuity and regularity of 3BS requires the following constraints on 3DAs:

$$\int D(\omega, \lambda) \{X_A, Y_A, \tilde{X}_A, \tilde{Y}_A, Z, W\} = 0, \quad \int D(\omega, \lambda) \omega \{Z, W\} = 0, \quad \int D(\omega, \lambda) \lambda \{Z, W\} = 0.$$

# Noncollinear LC configuration

- Generic kinematics. Proposed recently in [D. Melikhov (2022), D. Melikhov (2023)].
- An accurate account for the  $\mathcal{O}(\lambda_{B_s}/M_B)$  terms.  $\{\Psi_A, \Psi_V\} + 2 \times 6$  3DAs  $\{X_A^{(x,y)}, Y_A^{(x,y)}, \tilde{X}_A^{(x,y)}, \tilde{Y}_A^{(x,y)}, W(x,y), Z(x,y)\}$  parametrizing the kinematics-dependent part

$$\langle 0 | \bar{s}(y) G_{\nu\alpha}(x) \Gamma b(0) | \bar{B}_s(p) \rangle = \frac{f_B M_B^3}{4} \int D(\omega, \lambda) e^{-i\lambda y p - i\omega x p} \text{Tr} \left\{ \gamma_5 \Gamma (1 + \not{x}) \right. \\ \left. \times \left[ (p_\nu \gamma_\alpha - p_\alpha \gamma_\nu) \frac{1}{M_B} [\Psi_A - \Psi_V] - i\sigma_{\nu\alpha} \Psi_V - \frac{(x_\nu p_\alpha - x_\alpha p_\nu)}{xp} \left( X_A^{(x)} + \frac{\not{x}}{xp} M_B W^{(x)} \right) + \right. \right. \\ \left. \left. \frac{(x_\nu \gamma_\alpha - x_\alpha \gamma_\nu)}{xp} M_B \left( Y_A^{(x)} + W^{(x)} + \frac{\not{x}}{xp} M_B Z^{(x)} \right) - i\epsilon_{\nu\alpha\mu\beta} \frac{x^\mu p^\beta}{xp} \gamma^5 \tilde{X}_A^{(x)} + i\epsilon_{\nu\alpha\mu\beta} \frac{x^\mu \gamma^\beta}{xp} \gamma^5 M_B \tilde{Y}_A^{(x)} + \dots \right] \right\}$$

where the continuity and regularity of the 3BS requires the stronger constraints on 3DAs:

$$\int_0^{2\omega_0 - \lambda} d\omega X^{(x)}(\omega, \lambda) = 0 \quad \forall \lambda, \quad \int_0^{2\omega_0 - \omega} d\lambda X^{(y)}(\omega, \lambda) = 0 \quad \forall \omega, \\ \int_0^{2\omega_0 - \lambda} d\omega \omega^n Z^{(x)}(\omega, \lambda) = 0 \quad \forall \lambda, \quad \int_0^{2\omega_0 - \omega} d\lambda \lambda^n Z^{(y)}(\omega, \lambda) = 0 \quad \forall \omega, \quad n = 0, 1.$$

## Model for the $B$ -meson 3DAs

- Each of 3DAs is a function of  $\omega$  and  $\lambda$ , which are the fractions of  $B$ -meson momentum carried by gluon and light quark, respectively. The power scaling in  $\omega$  and  $\lambda$  is related to the conformal spins of the fields and remains the key property of the model.

### Local Duality model from [V. Braun, Y. Ji and A. Manashov (2017)]

Each of DAs is written as an expansion in functions with definite twist. The twists 3 and 4 are complemented by the higher twists 5 and 6 as following:

$$\left. \begin{aligned} \phi_3 &= \frac{105(\lambda_E^2 - \lambda_H^2)}{32\omega_0^2 M_B^2} \lambda \omega^2 (2\omega_0 - \omega - \lambda)^2 \theta(2\omega_0 - \omega - \lambda) \\ \phi_4 &= \frac{35(\lambda_E^2 + \lambda_H^2)}{32\omega_0^2 M_B^2} \omega^2 (2\omega_0 - \omega - \lambda)^3 \theta(2\omega_0 - \omega - \lambda) \end{aligned} \right\} \Psi_{A,V}(\omega, \lambda) = \frac{\phi_4 \pm \phi_3}{2},$$

$$\left. \begin{aligned} \psi_4 &\sim \lambda_E^2 \lambda \omega, \\ \tilde{\psi}_4 &\sim \lambda_H^2 \lambda \omega, \\ \phi_5 &\sim (\lambda_E^2 + \lambda_H^2) \lambda, \\ \psi_5 &\sim \lambda_E^2 \omega, \\ \tilde{\psi}_5 &\sim \lambda_H^2 \omega, \\ \phi_6 &\sim (\lambda_E^2 - \lambda_H^2), \end{aligned} \right\} \text{Together with } \phi_3, \phi_4 \text{ contribute to } \{X_A, Y_A, \tilde{X}_A, \tilde{Y}_A, W, Z\},$$

where the normalization parameters are constrained by the EOM as  $3\omega_0^2 = 14(2\lambda_E^2 + \lambda_H^2)$ .

- For  $\{X_A, Y_A, \tilde{X}_A, \tilde{Y}_A, W, Z\}$  the correction at large  $\omega$  and  $\lambda$  is applied  $\implies$  our corrected model reproduces well the collinear DA magnitudes and power behaviour at small  $\omega$  and  $\lambda$ .

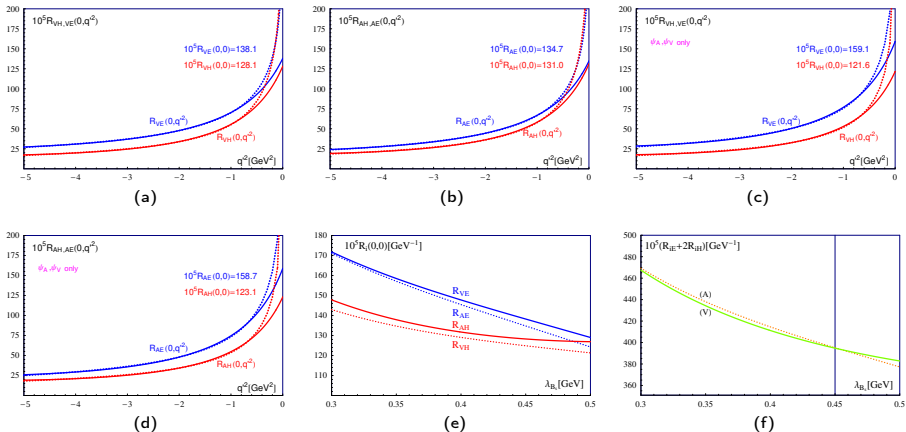

From QCD sum rules,

$$\lambda_H^2 \simeq 2\lambda_E^2$$

[A. Grozin,  
M. Neubert  
(1997)]

[T. Nishikawa,  
K. Tanaka  
(2014)]

Calculated form factors.  $\mathcal{H}_i^{\text{NF}}(0, q'^2) = R_{iE}(0, q'^2)\lambda_E^2 + R_{iH}(0, q'^2)\lambda_H^2$ ,  $i = A, V$

Calculated form factors.  $\mathcal{H}_i^{\text{NF}}(q^2, q'^2) = R_i(q^2, q'^2)\lambda_E^2$ ,

$$R_i(q^2, q'^2) = R_{iE}(q^2, q'^2) + 2R_{iH}(q^2, q'^2), \quad i = A, V$$

(a)

(b)

(c)

(d)

Pic.:  $R_i(q^2, 0)$  dependence (a,b) and  $R_i(0, q'^2)$  dependence (c,d) for  $i = V, A$ . Solid lines are the fits, and dashed lines present the results of direct calculations in the case of  $R_i(0, q'^2)$ .

# Results for the $\delta^{\text{NF}} C_7$ correction

Adding charm contributions to the top contributions leads to the following sum in the form factors  $A_i(q^2)$  [ $i = A, V$ ] parametrizing the total  $B_s \rightarrow \gamma l^+ l^-$  amplitude,

$$A_i(q^2) = \underbrace{\frac{2C_7}{q^2} m_b \left( F_{Ti}(q^2, 0) + F_{Ti}(0, q^2) \right)}_{\text{Penguin with } t\text{-quark}} + \underbrace{C_9 \frac{F_i(q^2, 0)}{M_B}}_{\text{Box with } t\text{-quark}} + \underbrace{8\pi^2 \frac{\mathcal{H}_i^F(q^2, 0)}{q^2}}_{\text{Factorizable charm}} + \underbrace{16\pi^2 Q_s Q_c \frac{\mathcal{H}_i^{\text{NF}}(q^2, 0) + \mathcal{H}_i^{\text{NF}}(0, q^2)}{q^2}}_{\text{Nonfactorizable charm}},$$

from which the relative correction is defined as

$$\delta_i^{\text{NF}} C_7 = 8\pi^2 Q_s Q_c \frac{C_2}{C_7 m_b} \rho_{cc}^{(i)}, \quad \text{where} \quad \rho_{cc}^{(i)} = \begin{cases} \frac{\mathcal{H}_i^{\text{NF}}(0, 0)}{F_{Ti}(0, 0)} & \text{for the case of } B_s \rightarrow \gamma\gamma \\ \frac{\mathcal{H}_i^{\text{NF}}(q^2, 0) + \mathcal{H}_i^{\text{NF}}(0, q^2)}{F_{Ti}(q^2, 0) + F_{Ti}(0, q^2)} & \text{for the case of } B_s \rightarrow \gamma l^+ l^- \end{cases}$$

• Numerically,  $\delta_A^{\text{NF}} C_7(q^2) \simeq \delta_V^{\text{NF}} C_7(q^2)$ .

• The nearest hadron singularities are at  $4M_K^2$  and  $M_{J/\psi}^2$ .

(a)

(b)

(c)

**Pic.:** (a) The functions  $\rho_{cc}^{(i)}$  at  $q^2 = 0$  versus  $\lambda_{B_s}$ ,  $i = V, A$ . (b-c) The relative NF correction  $\delta_V^{\text{NF}} C_7(q^2)$ : (b) the full result at  $0 < q^2 < 4M_K^2$ ; (c)  $\delta_V^{\text{NF}} C_7(q^2, 0)$  which dominates in  $\delta_V^{\text{NF}} C_7(q^2)$  at  $q^2 > 3 \text{ GeV}^2$ .

# Conclusions

(i) We derived and made use of the expression for the  $\langle VVA \rangle$  quark loop that is fully given in terms of the gluon field strength  $G_{\mu\nu}(x)$ . This has an advantage that no explicit use of any specific gauge for gluon field is necessary.

(ii) We studied the generic noncollinear 3BS of the  $B$ -meson. This quantity contains new Lorentz structures and new 3DAs compared to collinear and double-collinear 3BS. We took into account constraints from the requirement of analyticity and continuity and implemented proper modifications of the corresponding 3DAs  $X_i(\omega, \lambda)$  at large values of their arguments.

• We derived analytical expressions for the form factors  $\mathcal{H}_i^{\text{NF}}(q^2, q'^2)$ ,  $i = A, V, 3$ , describing NF contribution of charm loops to the amplitude of the  $B_s$  meson transition into two virtual photons,

$$\mathcal{H}_i^{\text{NF}}(q^2, q'^2) = \lambda_E^2 R_{iE}(q^2, q'^2) + \lambda_H^2 R_{iH}(q^2, q'^2), \quad i = A, V, 3.$$

We interpolated the results of  $\mathcal{H}_i^{\text{NF}}(q^2, q'^2)$  calculations in the  $(q^2, q'^2)$  rectangular region [sufficiently far from the quark thresholds] with a formula, which takes into account the presence of the poles at  $q^2 = M_{J/\psi}^2$  and  $q'^2 = M_\phi^2$ .

• The contribution of NF charm in  $B_s \rightarrow \gamma ll$  decay can be conveniently treated as the  $q^2$ -correction to the Wilson coefficient  $C_7$ , while the contribution of F charm — as the  $q^2$ -dependent correction to the Wilson coefficient  $C_9$ , such that both relative corrections are positive:

$$\Delta^{\text{NF}} C_7(q^2)/C_7 > 0 \text{ at } q^2 < 4M_K^2,$$

$$\Delta^{\text{F}} C_9(q^2)/C_9 > 0 \text{ at } q^2 < M_{J/\psi}^2.$$

• Our numerical results for the form factors  $\mathcal{H}_i^{\text{NF}}(q^2, q'^2)$  depend sizeably on the precise value of the parameter  $\lambda_{B_s}$  and exhibit about 10% accuracy for a fixed value of  $\lambda_{B_s}$ . For the  $B \rightarrow \gamma\gamma$  amplitude an explicit  $\delta C_7(\lambda_{B_s})$  dependence was calculated, from which for our benchmark point  $\lambda_{B_s}^0 = 0.45$  GeV we found

$$\delta^{\text{NF}} C_7(\lambda_{B_s}^0) = 0.045 \pm 0.004.$$

For  $\lambda_{B_s}$  in the range  $0.3 < \lambda_{B_s} \text{ (GeV)} < 0.6$ ,  $\delta C_7$  covers the range  $2 \div 10$  %.

## Deviation from the results for $B_s \rightarrow \gamma\gamma$ form factors in the HQ limit in the double collinear approximation

In the HQ limit in the double-collinear kinematics that dominates the NF charm-loop contribution to FCNC  $B$ -decay amplitudes, the leading contribution to the  $B_s \rightarrow \gamma\gamma$  amplitude is proportional to  $(\lambda_E^2 + \lambda_H^2)$ . This implies that

$$R_{VE} = R_{VH}, \quad R_{AE} = R_{AH}.$$

Our results show that these relations are sizeably violated by  $\mathcal{O}(\lambda_{B_s}/M_B)$  corrections that come into the game in the case of exact calculation [no HQ limit and generic kinematics]. Numerically, these deviations are around 20% ( $\psi_A, \psi_V$  only) and around 8% (all 3DAs included).
