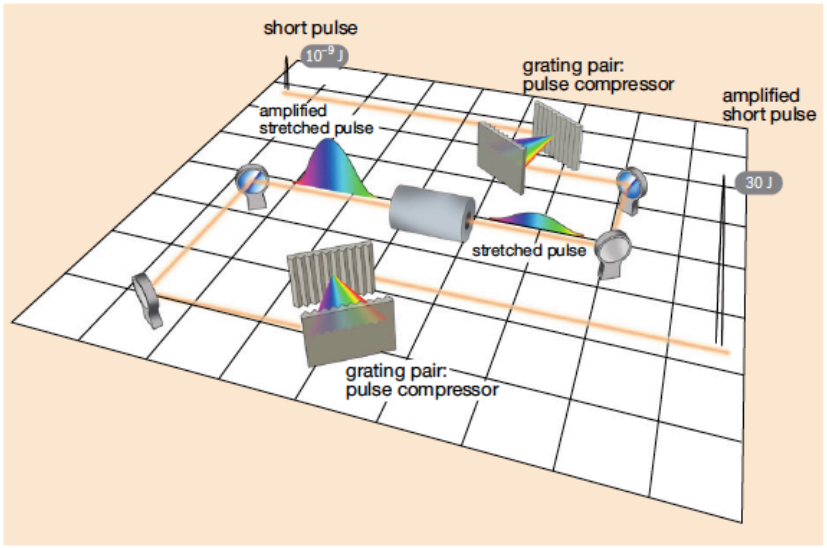
The advent of High-Power lasers thanks to the CPA

Institut national de la recherche scientifique

iPAT-LAB

Focus on: CPA

CPA: 25 years of intense laser pulses



Basic working principle of CPA. An initially very short but low energy laser pulse (top left) is first stretched, then amplified and then recompressed (bottom right). Numbers are indicative only.

The field of high-power lasers is booming (investments of over >1 B€ in 10 years!) (including INFN – FLAME/Eupraxia!)

[illegible] energy is transferred to 2×10^{12} protons of energy >10 MeV. The energy spectrum exhibits a sharp high-energy cutoff as high as 58 MeV on the axis of the beam which decreases in energy with increasing off axis angle. Proton induced nuclear processes have been observed and used to characterize the beam.

PACS numbers: 41.75.Jv, 07.77.Ka, 52.50.Jm

The generation of fast protons from laser irradiated solid surfaces is well understood [1,2] and attributable to electrostatic fields produced by hot electrons acting on protons from adsorbed hydrocarbons. An empirical power law relationship between the mean proton energy and intensity x (wavelength) [2] ($I\lambda^2$) was identified and proton energies up to a few MeV were observed for $I\lambda^2$ up to 10^{18} W cm^{-2} μm^2 in nanosecond pulses [1]. Scaling laws for the maximum energy were similarly derived [3].

Chirped pulse amplification (CPA) laser technology [4] has since enabled widespread generation of terawatt power and the first petawatt laser [5]. CPA lasers generate pulses in the range 20 fs to 1 ps. 10 MeV protons were observed with a 1 ps CPA laser at $I\lambda^2 = 10^{19}$ W cm^2 μm^2 consistent with the previous scaling [6,7].

New mechanisms of ion acceleration have been studied with CPA lasers. Ponderomotive pressure of the laser radiation causes radial acceleration when laser beams are focused in gas jets and subcritical density plasmas [8] and also axial acceleration into solid targets [9]. Coulomb explosion of molecules [10] and clusters [11] has produced energetic ions. The ion energies from these newly studied processes have been <1 MeV/nucleon.

We report a laser induced proton beam with much higher particle energy (up to 58 MeV). The maximum energy is about 2× higher than is given by extrapolating the previous scaling law [7] to the 30× higher intensity of this work. A distinctive feature is emission with good beam collimation perpendicular to the rear-unirradiated surface(s) of the target. Similar rear surface beaming of protons of energy <1 MeV was reported in nanosecond pulse CO_2 laser experiments [12]. Our observed high proton energies open up access to nuclear processes.

The experiments used a CPA laser system generating 1 PW pulses of 500 fs duration [5]. With $f/3$ parabolic mirror focusing, the peak intensity was 3×10^{20} W cm^{-2} in a focal spot of 9 μm FWHM with 30% of the energy inside the first minimum. Amplified spontaneous emission in a 4 ns period before the main pulse had 10^{-4} of the main pulse energy and there was a 3×10^{-4} prepulse 2 ns before the main pulse. This precursor radiation generated a plasma [illegible] optical interferometry [illegible] 3×10^{19} cm^{-3} in a plume 70 μm from a flat CH polymer target with an approximately exponential fall to lower densities having a scale [illegible]

The proton beam [illegible] film which changes through polymerization of a diacetylene active layer, from transparent to dark blue in proportion to the dose [illegible] 100 ergs/g). A 90° cone [illegible] and sheets of RC film was used. The cone is 4 cm deep at its apex, which [illegible] the laser axis [illegible] sphere. The RC film response was calibrated absolutely and the image data were analyzed by digital densitometry and transformed geometrically to produce contour plots of dose as a function of angle illustrated in Fig. 1.

The data in Fig. 1 show a collimated intense proton beam emitted perpendicular to the rear target surface of a Au target at 45° to the laser axis. Its angular width narrows to 10° in the image through 600 μm of Ta. The beam is rather uniform in intensity with near circular sharp boundaries. There is a low intensity wide-angle background, which is discussed elsewhere and is due to escaping relativistic electrons [14]. Similar results were seen for normal incidence, S polarization, and target thickness down to 20 μm. The proton beam profiles from CH targets have nonuniform edges and exhibit internal fine structure as illustrated in Fig. 2 for a 100-μm thick CH target at normal incidence. There was typically a 5 times greater proton induced dose recorded from CH relative to Au targets. Data

Abstract

Multi-MeV proton beams can be generated by irradiating thin solid foils with ultra-intense (>10^{18} W/cm^2) short laser pulses. Several of their characteristics, such as high bunch charge and short pulse duration, make them a complementary alternative to conventional radio frequency-based accelerators. A potential material science application is the chemical analysis

Laser-Accelerated Proton Beams as Diagnostics for Cultural Heritage

M. Barberio[1,2], S. Veltri[1], M. Scisciò[1,3] & P. Antici[1,3]

Received: 21 October 2015
Accepted: 07 December 2016
Published: 01 March 2017

This paper introduces the first use of laser-generated proton beams as diagnostic for materials of interest in the domain of Cultural Heritage. Using laser-accelerated protons, as generated by interaction of a high-power short-pulse laser with a solid target, we can produce proton-induced X-ray emission spectroscopies (PIXE). By correctly tuning the proton flux on the sample, we are able to perform the PIXE in a single shot without provoking more damage to the sample than conventional methodologies. We verify this by experimentally irradiating materials of interest in the Cultural Heritage with laser-accelerated protons and measuring the PIXE emission. The morphological and chemical analysis of the sample before and after irradiation are compared in order to assess the damage provoked to the artifact. Montecarlo simulations confirm that the temperature in the sample stays safely below the melting point. Compared to conventional diagnostic methodologies, laser-driven PIXE has the advantage of being potentially quicker and more efficient.

Laser-PIXE

Laser driven Particle Induced X-ray Emission: source development and X-ray spectral/spatial analysis

The PIXE (Particle Induced X-ray Emission) is a multi-elemental, quantitative, highly sensitive (trace elements with concentrations in parts-per-million), rapid, non-invasive and non-destructive analysis technique to determine the composition of surface layers of a sample. The technique is based on spectroscopy of the characteristic X radiation emitted by each atom following irradiation with proton/ion beams. PIXE requires protons with MeV energies (2-3 MeV typically) that are currently produced with particle accelerators whose dimensions (and costs) represent a limit for the application of the same technique outside of large research in-

Italia-Québec, la cooperazione va su "Science Advances"

Data: 11/10/2017

Nell'ambito del **Programma esecutivo di cooperazione culturale, scientifica e tecnologica tra Italia e Québec** per il periodo 2017-2019, un'innovativa ricerca nel campo delle tecnologie applicate alla tutela del patrimonio culturale, guidata dal professore **Patrizio Antici**, studioso italiano in forza all'**Institut National de la Recherche Scientifique (INRS) del Québec**, ha ottenuto la pubblicazione sulla prestigiosa rivista "***Science Advances***".

Antici, assieme ai suoi collaboratori e a un gruppo di ricerca internazionale, che vede coinvolta anche l'Università della Calabria, l'acceleratore di particelle francese AIFIRA ed il laboratorio Greco FORTH, ha sviluppato un nuovo strumento diagnostico per esaminare lo stato di conservazione delle opere pittoriche: il metodo di ricerca impiega la tecnologia laser per spiegare come mai alcuni pigmenti di alcune opere pittoriche, tra cui i celebri Girasoli di Van Gogh, abbiano perso la loro lucentezza originaria nel corso del tempo, diventando via via più scuri.

Antici - laureato in ingegneria presso la Sapienza Università di Roma, con dottorato in fisica presso l'Ecole Polytechnique (Francia) e dottorato in ingegneria presso la Sapienza spiega: "La nuova
