The three pillars of cosmology

- Background: no perturbations, very simple
- Linear perturbations: small amplitudes, important for large scales
- Nonlinear perturbations: very difficult to treat analytically, mainly done with approximate methods or N -body simulations. It's the “holy grail” of theoretical cosmology

Why and how modify gravity

But there are problems

- Naturalness: why is the value of Λ so small?
- Coincidence: why is it important now?
- Tensions between low- and high- z probes (H_0 , σ_8 , A_{lens})

Solutions

- 1 It is the cosmological constant (**anthropic principle**, **string landscape**) - **it agrees with data, but unsatisfactory**
- 2 Supernova data **are wrong** (**distance-duality relation**) - **unlikely**
- 3 Violation of the Copernican principle (**LTB models**) or problems with GR (**backreaction**) - **unlikely**
- 4 Scalar field evolving (**dark energy**)
- 5 GR is wrong (**modified gravity**)

What do dark energy and modified gravity do?

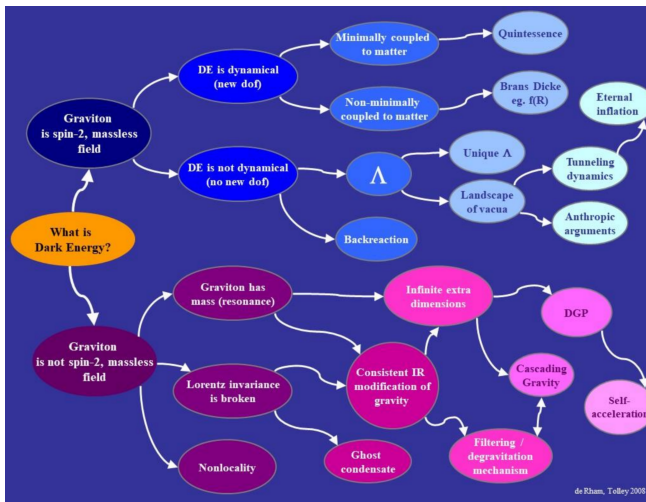

- Determine structure formation and evolution
- Change background evolution
- Modify linear perturbations
- Strongly affect nonlinear perturbations
- May help to resolve cosmological anomalies?
- Most importantly, they help us to better understand gravity

Horndeski models

$$\mathcal{L}_2 = G_2(\phi, X)$$

$$\mathcal{L}_3 = G_3(\phi, X)\square\phi$$

$$\mathcal{L}_4 = G_4(\phi, X)R + G_{4,X} [(\square\phi)^2 - (\nabla_\mu\nabla_\nu\phi)(\nabla^\mu\nabla^\nu\phi)]$$

$$\mathcal{L}_5 = G_5(\phi, X)R(\nabla^\mu\nabla^\nu\phi) - \frac{1}{6}G_{5,X} [(\square\phi)^3 - 3\square\phi(\nabla_\mu\nabla_\nu\phi)(\nabla^\mu\nabla^\nu\phi) + 2(\nabla^\mu\nabla_\alpha\phi)(\nabla^\alpha\nabla_\beta\phi)(\nabla^\beta\nabla_\mu\phi)]$$

- Most general theory with 2nd order e.o.m.
- It encompasses many models studied in the literature
- Perturbations described by H plus 4 free functions of time, $\alpha_K, \alpha_B, \alpha_M, \alpha_T$
- Linear combinations of G_i and their derivatives
- Physical meaning, possibility of constraining them with observations
- GW constraint implies $\alpha_T \approx 0$. This rules out a large number of Horndeski models [$G_5 \approx \text{constant}$ and $G_4 = G_4(\phi)$]

Effective Field Theory (EFT) of dark energy (DE)

- Similar approach to particle physics
- Valid only on the scales of interest
- Ignores degrees of freedom on smaller scales
- It requires a separation of scales
- There are different, but equivalent approaches
- Use 3+1 split (uniform scalar field hypersurfaces)
- Geometry described by ${}^3R_{\mu\nu}$, extrinsic curvature $K_{\mu\nu}$, g^{00} or lapse N

- $H(t)$ [$w_{\text{ds}}(t)$]: background evolution
- $\alpha_K(t)$: “kineticity” - kinetic energy, large $\alpha_K \rightarrow$ small c_s^2
- $\alpha_B(t)$: “braiding” - mixing of kinetic terms and metric, contributes to DE clustering
- $\alpha_M(t)$: “running rate of the Planck mass” $M^2(t)$ - $H\alpha_M = d \ln M^2/dt$, contributes to anisotropic stress
- $\alpha_T(t)$: “tensor speed excess” - $c_{\text{gw}}^2/c^2 = 1 + \alpha_T$, contributes to anisotropic stress
- $\alpha_H(t)$: “beyond Horndeski” - higher order term that cancels in e.o.m.
- Stability conditions: $c_s^2 > 0$, $c_T^2 > 0$, $\alpha = \alpha_K + 6\alpha_B^2 > 0$

The Universe today

Spherical collapse model (SCM)

- Describes the evolution of perturbations on non-linear scales
- Based on the fluid approach
- Main assumptions
 - 1 Sphericity
 - 2 Isolated perturbations
 - 3 Top-hat density profile
- Easy to use for DE, more complications for MG
- Provides physical quantities related to the halo mass function

Assume a spherical cow of uniform density.

...while ignoring the effects of gravity.

...in a vacuum.

bastard theoretical physicists

How do you sleep at night?

Physics of the SCM

- ① Initial perturbation expands following the Hubble flow
- ② Overdense regions slow down and reach a maximum size
- ③ Perturbation recollapses to a (mathematical) point
- ④ Virialization not native in the formalism
- ⑤ Physical quantities returned: $z_{\text{ta}}, \zeta = 1 + \delta^{\text{NL}}(z_{\text{ta}}), z_{\text{vir}}, R_{\text{vir}}/R_{\text{ta}}, \Delta_{\text{v}}$

Theoretical results and comparison with simulations

Theoretical results and comparison with simulations

FP et al., 2014

Conclusions and future directions

- Current data compatible with Λ CDM, but future ones can constrain DE and MG models
- Discrepancies between early and late time (large and small scales)
- SCM in good agreement with simulations
- Long-term goal: Self-consistent numerical library to be used in cosmology
