- ➢ Radiation damage in semiconductors: a very brief overview
- ➢ Results
	- ➢ Damage recombination at ns times after a cascade
	- ➢ Energy release spectrum of events
	- $\triangleright$  Avalanche mechanism of annealing
	- ➢ Time scale of annealing events at cryogenic temperatures
- ➢ Conclusion

#### **Radiation damage in semiconductors: it is not Frenkel pairs**

- $\triangleright$  We have studied damage in a wide range of metals, semiconductors and ionic material over the last 30 years
- ➢ For semiconductors, key message: primary damage is practically never simple Frenkel pairs (vacancies and interstitials) 1000 eV Si recoil in Si

[K. Nordlund *et al*, Phys. Rev. B 57, 7556 (1998); K. Nordlund *et al,* J. Nucl. Mater. 512, 450 (2018)]

**HELSINGIN YLIOPISTO** HELSINGFORS UNIVERSITET UNIVERSITY OF HELSINKI

#### **Our previous works on relation of defects and dark matter**

 $\triangleright$  We have previously shown that DM interactions with a single crystalline detector of known orientation may lead to a distinct daily variation in DM observations

[F. Kadribasic et al,, Phys. Rev. Lett. 120, 111301 (2018); F. Kadribasic et al, Journal of Low Temperature Physics 5-6, 1146 (2018); M. Heikinheimo et al,, Phys. Rev. D 99, 103018 (2019); S. Sassi et al, Phys. Rev. D 104, 063307 (2021); S. Sassi et al, Phys. Rev. D. 106 (2022) 083009 M. Heikinheimo et a, Phys. Rev. D 106 (2022) 083009]

Department of Physics Prof. Kai Nordlund

#### **Recent observations: low-energy excess and defects in solids??**

➢ Defects produced by radiation or other means store energy in solids

➢ Could the DM excess signal be somehow related to this?

[M. Heikinheimo et al, Phys. Rev. D **106**, 083009 (2022)]

**HELSINGIN YLIOPISTO IGFORS UNIVERSITET UNIVERSITY OF HELSINKI** 

#### **Our hypothesis to be tested**

- ➢ Could recombination of damage induced by radioactive impurities in the materials or surroundings be a source of energy release
	- ➢ Decay of radioactive impurity isotopes are a known source of background signal in detectors
	- $\triangleright$  Radioactive impurities are practically impossible to avoid
	- $\triangleright$  Could there be a delayed signal from the damage production?
- ➢ We set out to test this systematically, using our best understood material Si as a basis

### **Annealing simulations, example animation**

- $\triangleright$  Cascade + its annealing at 300 K for 3 ns
	- $\triangleright$  Extent of damage after cascade shown with dashed lines
- ➢ Major annealing observed in the time intervals
	- $\geq 20-30$  ps
	- $>$  50-60 ps
	- ➢ 200-300 ps
	- $\geq 900$  ps  $-1$  ns

Segment of a cascade induced by a 5 keV recoil in Si + its annealing at 300 K

**HELSINGIN YLIOPISTO HELSINGFORS UNIVERSITET** UNIVERSITY OF HELSINKI

#### **Systematic analysis of annealing energy release**

- $\triangleright$  The annealing runs were systematically analyzed for number of defects and potential energy
- ➢ The results show rapid annealing within first  $\sim$  100 ps from damage event, but after that continued intermittent annealing events for as long the simulations were ran – up to 100 ns

**HELSINGIN YLIOPISTO** HELSINGFORS UNIVERSITET UNIVERSITY OF HELSINKI

#### **Temperature dependence**

- ➢ At 600 K such annealing as been reported many times before
- ➢ What was surprising was that similar annealing events were observed even at 100 K and below!

**HELSINGIN YLIOPISTO HELSINGFORS UNIVERSITET** UNIVERSITY OF HELSINKI

Department of Physics Prof. Kai Nordlund

#### **Statistics of energy release**

- ➢ Taking the energy release peaks from all the independent annealing+quenching runs, one can get a statistical distribution of the energy release
	- ➢ Remarkably, the slope almost independent of temperature
	- $\triangleright$  Slope also remains the same when the quantum mechanical zero point vibrations are taken into account

#### **Statistics of energy release: comparison with experiments**

- ➢ This data can be compared directly with the experimental low-energy excess exponential tail
	- ➢ Outstanding agreement!

**HELSINGIN YLIOPISTO NGFORS UNIVERSITET** UNIVERSITY OF HELSINKI

#### **Why is the statistics of energy release independent of temperature?**

➢ To understand why the energy release has practically no dependence on temperature, we analyzed in detail some individual recombination events

➢ Atoms plotted with displacement color scale

#### **A recombination avalanche**

- ➢ We observed that the large energy release events are always at low-temperatures preceded by crossing a very small  $\sim 0.1$ eV) barrier **Trigger**
- ➢ This initial small rearrangement of atoms slightly heats up the immediate surroundings, which can **trigger** a much larger atom rearrangement and hence energy release
	- $\triangleright$  This is analogous to critical phenomena, such as avalanches in sand piles or snow
- ➢ We hence call this a "recombination avalanche" effect
	- ➢ Such events are observed up to the maximum simulation time of 30 ns – no reason there would be an upper time limit

#### **Animation of recombination avalanche**

**HELSINGIN YLIOPISTO HELSINGFORS UNIVERSITET** UNIVERSITY OF HELSINKI

#### **Timescale of events**

- $\triangleright$  In purely classical molecular dynamics, the rate of energy release does slow down with temperature
- ➢ At the cryogenic detector temperature of 0.04 K, the rate would be astronomically high (pun intended)
- ➢ However, taking into account quantum vibrations, we observe annealing effects even at 0.05 K with a decay time constant of the order of microseconds
	- ➢ If the **entire macroscopic**  detector e.g. undergoes a radioactive decay **anywhere**  at rates < 1 event/microsecond, this predicts a roughly constant signal if the time resolution of the detectors is above microseconds

HELSINGIN YLIOPISTO **GFORS UNIVERSITET UNIVERSITY OF HELSINKI** 

#### **Conclusion**

- $\triangleright$  Energy release from defects in Si follow a very similar exponential energy dependence as the experimentally observed "low-energy excess" in semiconductor detectors
	- ➢ Defects could be induced by radiactive impurities or possibly also be associated with cracks or other inherent defects
- $\triangleright$  The energy release is almost independent of temperature due to a "recombination avalanche" effect
- ➢ Outlook: nanocalorimetry and/or pulsed ion beam experiments could be used to confirm the effect?

**HELSINGIN YLIOPISTO HELSINGFORS UNIVERSITET UNIVERSITY OF HELSINKI** 

#### **Actually: we are the energetic particles hitting the dark matter!**

**230 km/s**

#### **Kinetic energy transfer from dark matter to ordinary atom nucleus**

➢ Estimation of order of magnitude of energy transfer:

 $\triangleright$  **Assume** dark matter particle of mass  $m_1 = 1$  GeV/c<sup>2</sup>

 $\geq$  220 km/s corresponds to  $E_{DM}$  = 269 eV

- ➢ A typical low-energy ion gun energy!
- $\triangleright$  From DM density of  $\sim$  1 GeV/cm<sup> $\land$ </sup>3 given by astronomical models, we can deduce our bodies pass **through 30 billion DM particles per second.**

 $\triangleright$  Then we can calculate the energy transfer in a head on collision from basic kinematics to a Si atom  $(m<sub>2</sub>=28 \text{ u})$ :

$$
T = \frac{4m_1m_2}{(m_1+m_2)^2}E_{DM} = 38 \text{ eV}
$$

 $\triangleright$  This is in the range of threshold displacement energies in Si!

**HELSINGIN YLIOPISTO IGFORS UNIVERSITET** UNIVERSITY OF HELSINKI

#### **Relative movement effects**

- ➢ The motion of the sun around the galaxy would give a constant level of recoil energies to ordinary matter from the "WIMP wind"
	- $\triangleright$  This would be difficult to distinguish from any number of regular background radiation sources
- $\triangleright$  However, any position on earth rotates around its axis
	- $\triangleright$  This should give a daily variation in the signal if measured **in a direction sensitive way** from a crystal fixed on earth
- ➢ Moreover: the earth rotates around the sun at 30 km/s
	- $\triangleright$  This should give an annual variation in the signal in a given direction

[Fig: wikipedia]

**HELSINGIN YLIOPISTO** HELSINGFORS UNIVERSITET UNIVERSITY OF HELSINKI

#### **Key idea: utilize the threshold displacement energy in detection**

- $\triangleright$  In case it so happens that the energy transfer from dark matter to ordinary matter is **around the threshold displacement energy**, then:
	- ➢ If you make a single-crystal highly sensitive detector, and fix it on earth, the dark matter detection signal should vary daily!
		- $\triangleright$  Simplified argument: if the relative motion of the detector w.r.t. the dark matter background is in a direction such that the energy transfer is just below the threshold, no signal, above: clear signal
	- $\triangleright$  In reality if is of course a convolution of the kinetic energy distribution of dark matter itself, the movement of the earth and the threshold displacement energy surface

#### **Our work: systematic analysis of effect**

- ➢ Formulate a way to calculate transfer of dark matter particles to ordinary ones
- ➢ 1. Distribution of dark matter particle velocities (with galactic escape velocity truncation) in galaxy

$$
f_{\rm gal}(\mathbf{v}) = \begin{cases} & \frac{1}{N_{\rm esc}(2\pi\sigma_v^2)^{3/2}} \exp\left[-\frac{\mathbf{v}^2}{2\sigma_v^2}\right] & \text{if } |\mathbf{v}| < v_{\rm esc} \\ 0 & \text{if } |\mathbf{v}| \ge v_{\rm esc} \end{cases}
$$

➢ 2. Radon transform to get to lab coordinates on Earth from motion and rotation of Earth, and movement of solar system around the galaxy

$$
\hat{f}_{\text{lab}}(v_{\text{min}}, \hat{q}; t) = \frac{1}{N_{\text{esc}} \sqrt{2\pi\sigma_{\nu}^2}} \times \left[ \exp\left( -\frac{|v_{\text{min}} + \hat{q} \cdot v_{\text{lab}}|^2}{2\sigma_{\nu}^2} \right) - \exp\left( -\frac{v_{\text{esc}}^2}{2\sigma_{\nu}^2} \right) \right]
$$
