Test of amorphous silicon detectors on the Trento Proton Beam Line

Hydrogenated amorphous silicon (a-Si:H) is a well

known material for its radiation resistance and for the possibility

of deposition on flexible substrates like Polyimide (PI). The HASPIDE collaboration is developing a-Si:H devices both for

dosimetry of clinical beams than flux measurement of other beam types.

In this framework a test has been carried out at the Trento Proton Beam Line to test the capabilities of the prototypes in measuring the proton fluxes. Some resulta on device sensitivity, linearity of the reponse and measurement uncertainty will be presented.
