# He B1236 Monte Carlo truth studies

Analysis meeting 22.04.2024

---

Francesco Rossi, Prof. P. Zuccon

# Applied selection:

IsPhysicsTrigger

TOF:  $N^{\circ}$  beta clusters = 4

TOF:  $\chi^2_{\text{COO}} < 4$

TRK:  $N^{\circ}$  of track  $\geq 1$

TRK:  $q_{\text{inner}} \in [1.7, 2.4]$

TRK:  $q_{L1} \in [1.6, 3.0]$

TRK: L1 && L2 && (L3||L4) && (L5||L6) && (L7||L9)

TRK:  $\chi^2_{\text{inner}}(\text{GBL}) \leq 10$

TOF:  $q^{\text{upper-tof}} \in [1.5, 3.0]$

TOF:  $q^{\text{lower-tof}} > 1.5$

IsPhysicsTrigger	20576755	0.4411

ChargeLowerTof(1.5,30)	3737905	0.0801

## Work strategy:

### The goal:

Identify charge confusion sources (i.e. *large angle scattering*) using Monte Carlo truth.

### Work strategy:

1. Use the tracks propagator in the AMS-02 magnetic field (extracted by P. Zuccon from gbatch).
2. Get the initial conditions for the propagator from the MC truth of primary at L2.
3. Follow the progression of the primary inside the inner tracker.
4. Compare the MC truth with the propagator output.
5. Primary are divided into two classes depending on the reconstructed rigidity with the inner tracker.

# AMS propagator

GitLab repository: [AMSTkProp](#)

Initial conditions:

1. position  $(x_{in}, y_{in}, z_{in})$ .
2. direction  $(\vartheta_{in}, \varphi_{in})$ .
3. particle charge.
4. particle rigidity.
5. particle mass.

Outputs:

1. position  $(x_{out}, y_{out}, z_{out})$ .
2. direction  $(\vartheta_{out}, \varphi_{out})$ .

Given the initial conditions, the track is propagated up to a specified z coordinate.

**Energy losses and multiple scattering (MS) are not considered.**

# MC truth and propagator output comparison

**Primary true position and momentum** can be retrieved **at each of the inner tracker layer**.

MC truth and propagator output can be confronted **as function of generated rigidity**.

The differences are expected to be small, thus the logarithm of the difference has been used (i.e.  $\log_{10}(|Y^{\text{prop}} - Y^{\text{true}}|)$ ).

Primaries are divided in **two classes based on the inner reconstructed rigidity**:

# Y coordinate at L3

$R_{\text{inner}} < 0$

$R_{\text{inner}} > 0$

# Y coordinate at L8

$R_{\text{inner}} < 0$

$R_{\text{inner}} > 0$

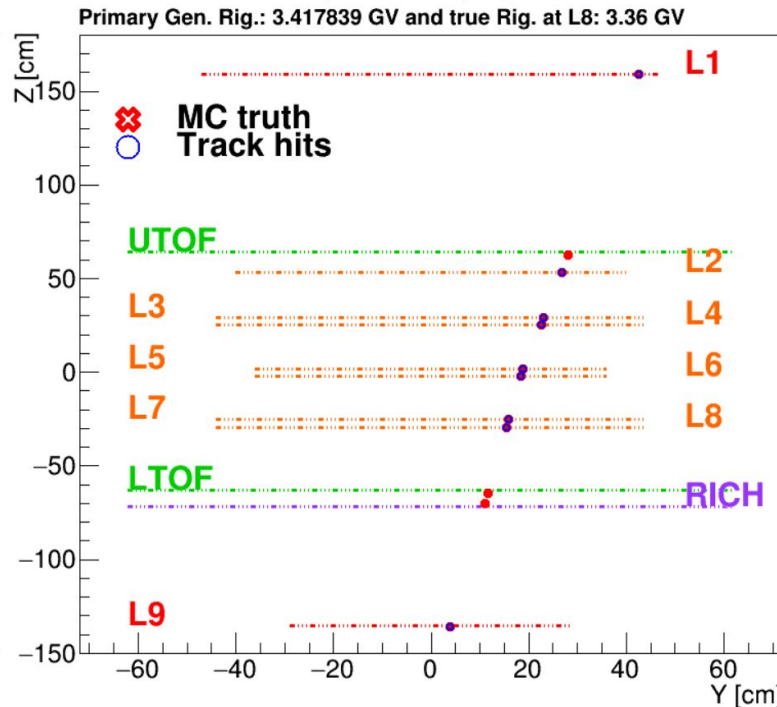

# Simple event display for $R_{\text{inner}} < 0$ and $\log_{10}(|Y^{\text{prop}} - Y^{\text{L8}}|) > 0.1$

Z-X plane display

Z-Y plane display

$R_{\text{true}} = 3.41 \text{ GV}$

$R_{\text{inner}}^{\text{rec}} = -0.622 \text{ GV}$

$R_{\text{inner-L1}}^{\text{rec}} = -0.638 \text{ GV}$

## Next steps

1. Increase statistics and run over all the He B1236 ntuples.
2. Look directly at outliers events with an event display.
3. Propagate tracks with the wrong-reconstructed rigidity and evaluate residuals with MC truth and reconstructed track.

## Next steps

1. Increase statistics and run over all the He B1236 ntuples.
2. Look directly at outliers events with an event display.
3. Propagate tracks with the wrong-reconstructed rigidity and evaluate residuals with MC truth and reconstructed track.

**Thank you for your  
attention!**
