Hall C
entrance

“Vessel Dome + Lifting Beams” sub-assembly

DS20k_ID_VESS_TopDome+Beams.SLDASM

- **One single orientation is allowed.**
 - ▶ Lifting Beams should align properly with hooks of the two external crane in Hall C;
 - ▶ Dome ports should align with cryostat ports;
 - ▶ **3 HV ports create an asymmetry.**

Proposed **reference frame** to be used for ID model and proposed **labeling scheme** to identify the eight sides of the octagonal components (agreed with D. Rogowsky)

entrance

Relative constraints between ID sub-assemblies

“Calibration Pipes” sub-assembly

DS20k_ID_CAL__Cal.SLDASM

- Four orientations are in principle allowed.
 - The assembly has a 90 degree symmetry (if “upper U pipe” or “lower U pipe” can be swapped);
- The Calibration Pipe orientation constraints the orientation of the BOP once the pipe connection to BOP are put in place.
 - *the U brackets shall not conflict with vPDU locations*
 - *the U brackets shall match the brackets holes in the BOP.*

“Vertical Support Rods” sub-assembly

DS20k_ID_SUPP__Support.SLDASM

- Four orientations are in principle allowed.
 - The location of the rods in the space is defined by the dome orientation;
 - The 8-rod-assembly has a 90 degree symmetry;
- The Vertical Support Rods orientation constraints the allowed orientations of the TOP and BOP.

“TOP” sub-assembly

DS20k_ID_MULT__TOPFull.SLDASM

- Four orientations are in principle allowed.
 - ▶ The vertical rod positions are defined
 - ▶ The TOP assembly has a 90 degree symmetry as far as mounting is concerned;
- The TOP orientation:
 - ▶ fully constraints the orientation of the ANODE due to the central post;
 - ▶ *The push/pull system works with the Anode post being in any of the four quadrants (confirmed by Nic).*
 - ▶ defines (weakly) the cable bundles location. Cables leaves the TOP through 6 sides out of 8.
 - ▶ *Constraints (weakly) the BOP orientation through cable bundles*

Central post hole

“ANODE” sub-assembly

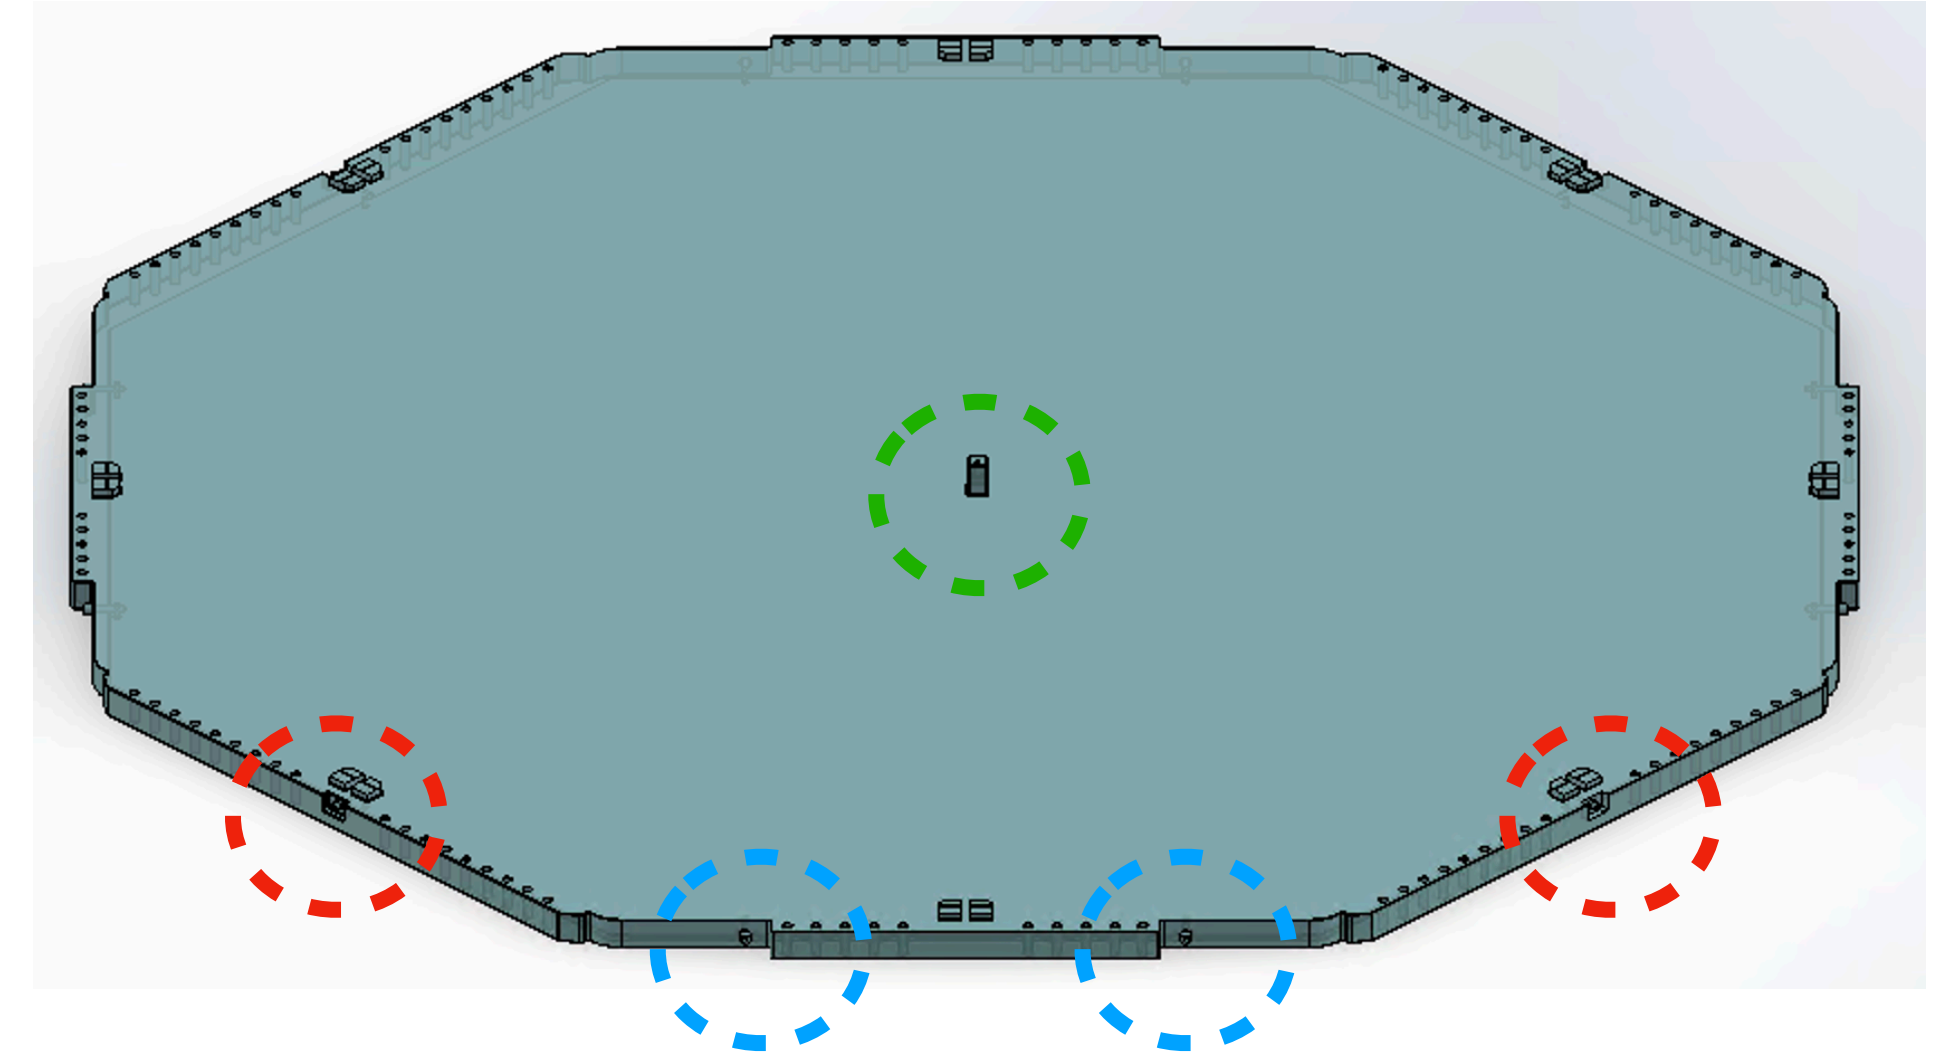

DS20k_ID_ANOD__Anode.SLDASM

- Its orientation is fully constrained by the orientation of the TOP due to the central post;
- The ANODE orientation constraints:
 - ▶ the possible orientations of the BARREL:
 - *the levelmeter ports on the ANODE/BARREL should match (90 degree symmetry).*
 - ▶ the possible orientations of the CAL pipes (conflict with levelmeter ports)
 - ➔ possible locations of the bubbler and of the boiler;
 - ▶ the possible orientations of the grid;
 - *the ANODE HV connection should align with grid segments without faraday cage (no wires).*

Levelmeter ports

Bubbler/boiler ports

Central post

“BARREL” sub-assembly

DS20k_ID_MULT__Barrel+FC.SLDASM

- Its orientation is constrained by the orientation of the ANODE and by the HV feedthrough for the top-most ring
 - The assembly has a 90 degree symmetry (mostly due to the levelmeter ports);
- The BARREL orientation constraints:
 - the possible orientations of the GRID:
 - *through the HV connector (shall we keep it on the HV port side)*
 - LAr inlet ports conflict with CAL pipes → **need to shift them**
 - the possible locations of the boiler (due to a special port on a single panel);
 - the possible orientations of the CATHODE (through the locking feet);
 - the possible orientations of the IV frames (some frames will have to embed cable trays);

LAr Inlet Top Row

LAr Inlet Central Row

Double port: LAr Inlet+Levelmeter

Boiler port (ona. Single panel)

“GRID” sub-assembly

DS20k_ID_GRID_Grid.SLDASM

- Its orientation is constrained by:
 - ▶ the centering guides on the BARREL shelf;
 - ▶ the location of the HV connector on BARREL external lip;
 - ▶ the location of the ANODE ground connector (still to be designed).

“CATHODE” sub-assembly

DS20k_ID_CATH__Cathode.SLDASM

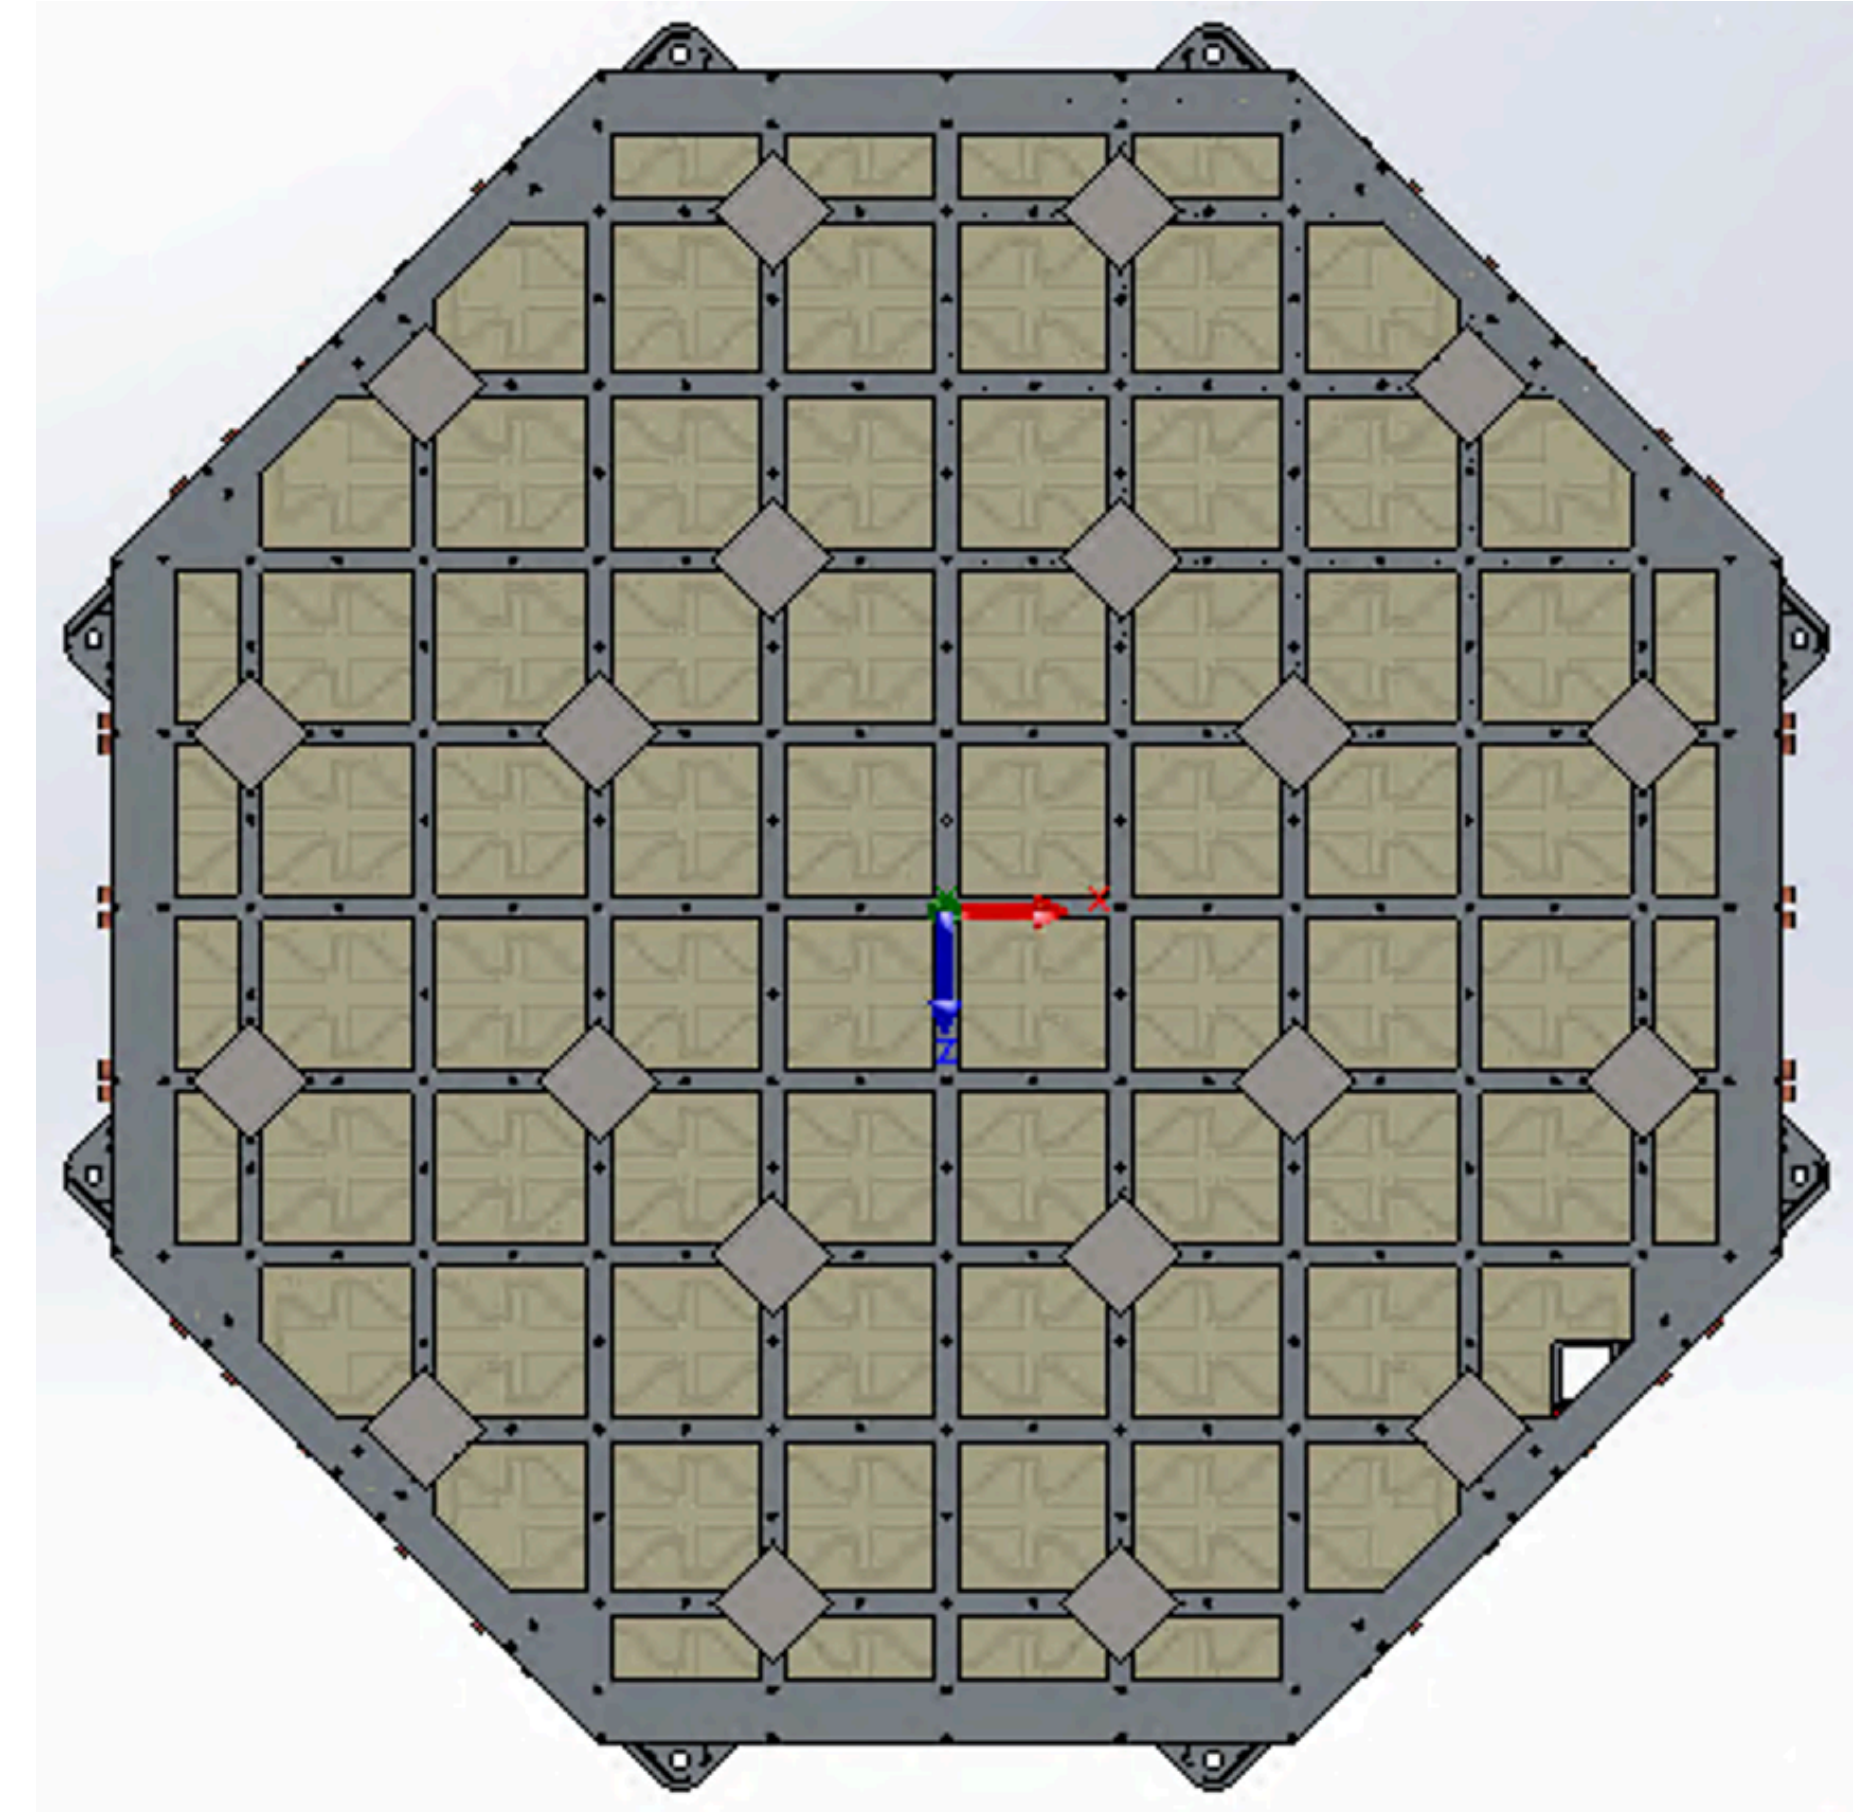

- Its orientation is fully constrained by the orientation of the DOME
 - The HV CONE should stay on the opposite side of the DOME HV ports
- The CATHODE orientation:
 - defines uniquely the orientation of the BOP
 - *thought the opening for the HV cone and through the feet*

“BOP” sub-assembly

DS20k_ID_MULT__BOPFull.SLDASM

- Its orientation is fully constrained by the CATHODE orientation brought the HV CONE
- Partially constrained by the CAL pipes
- The BOP orientation constraints:
 - ▶ defines (weakly) the cable bundles location. Cables leaves the BOP through 6 sides out of 8.
 - ▶ *Constraints (weakly) the TOP orientation through cable bundles*

Assembly in the Hall C reference frame

Moving to the global reference frame

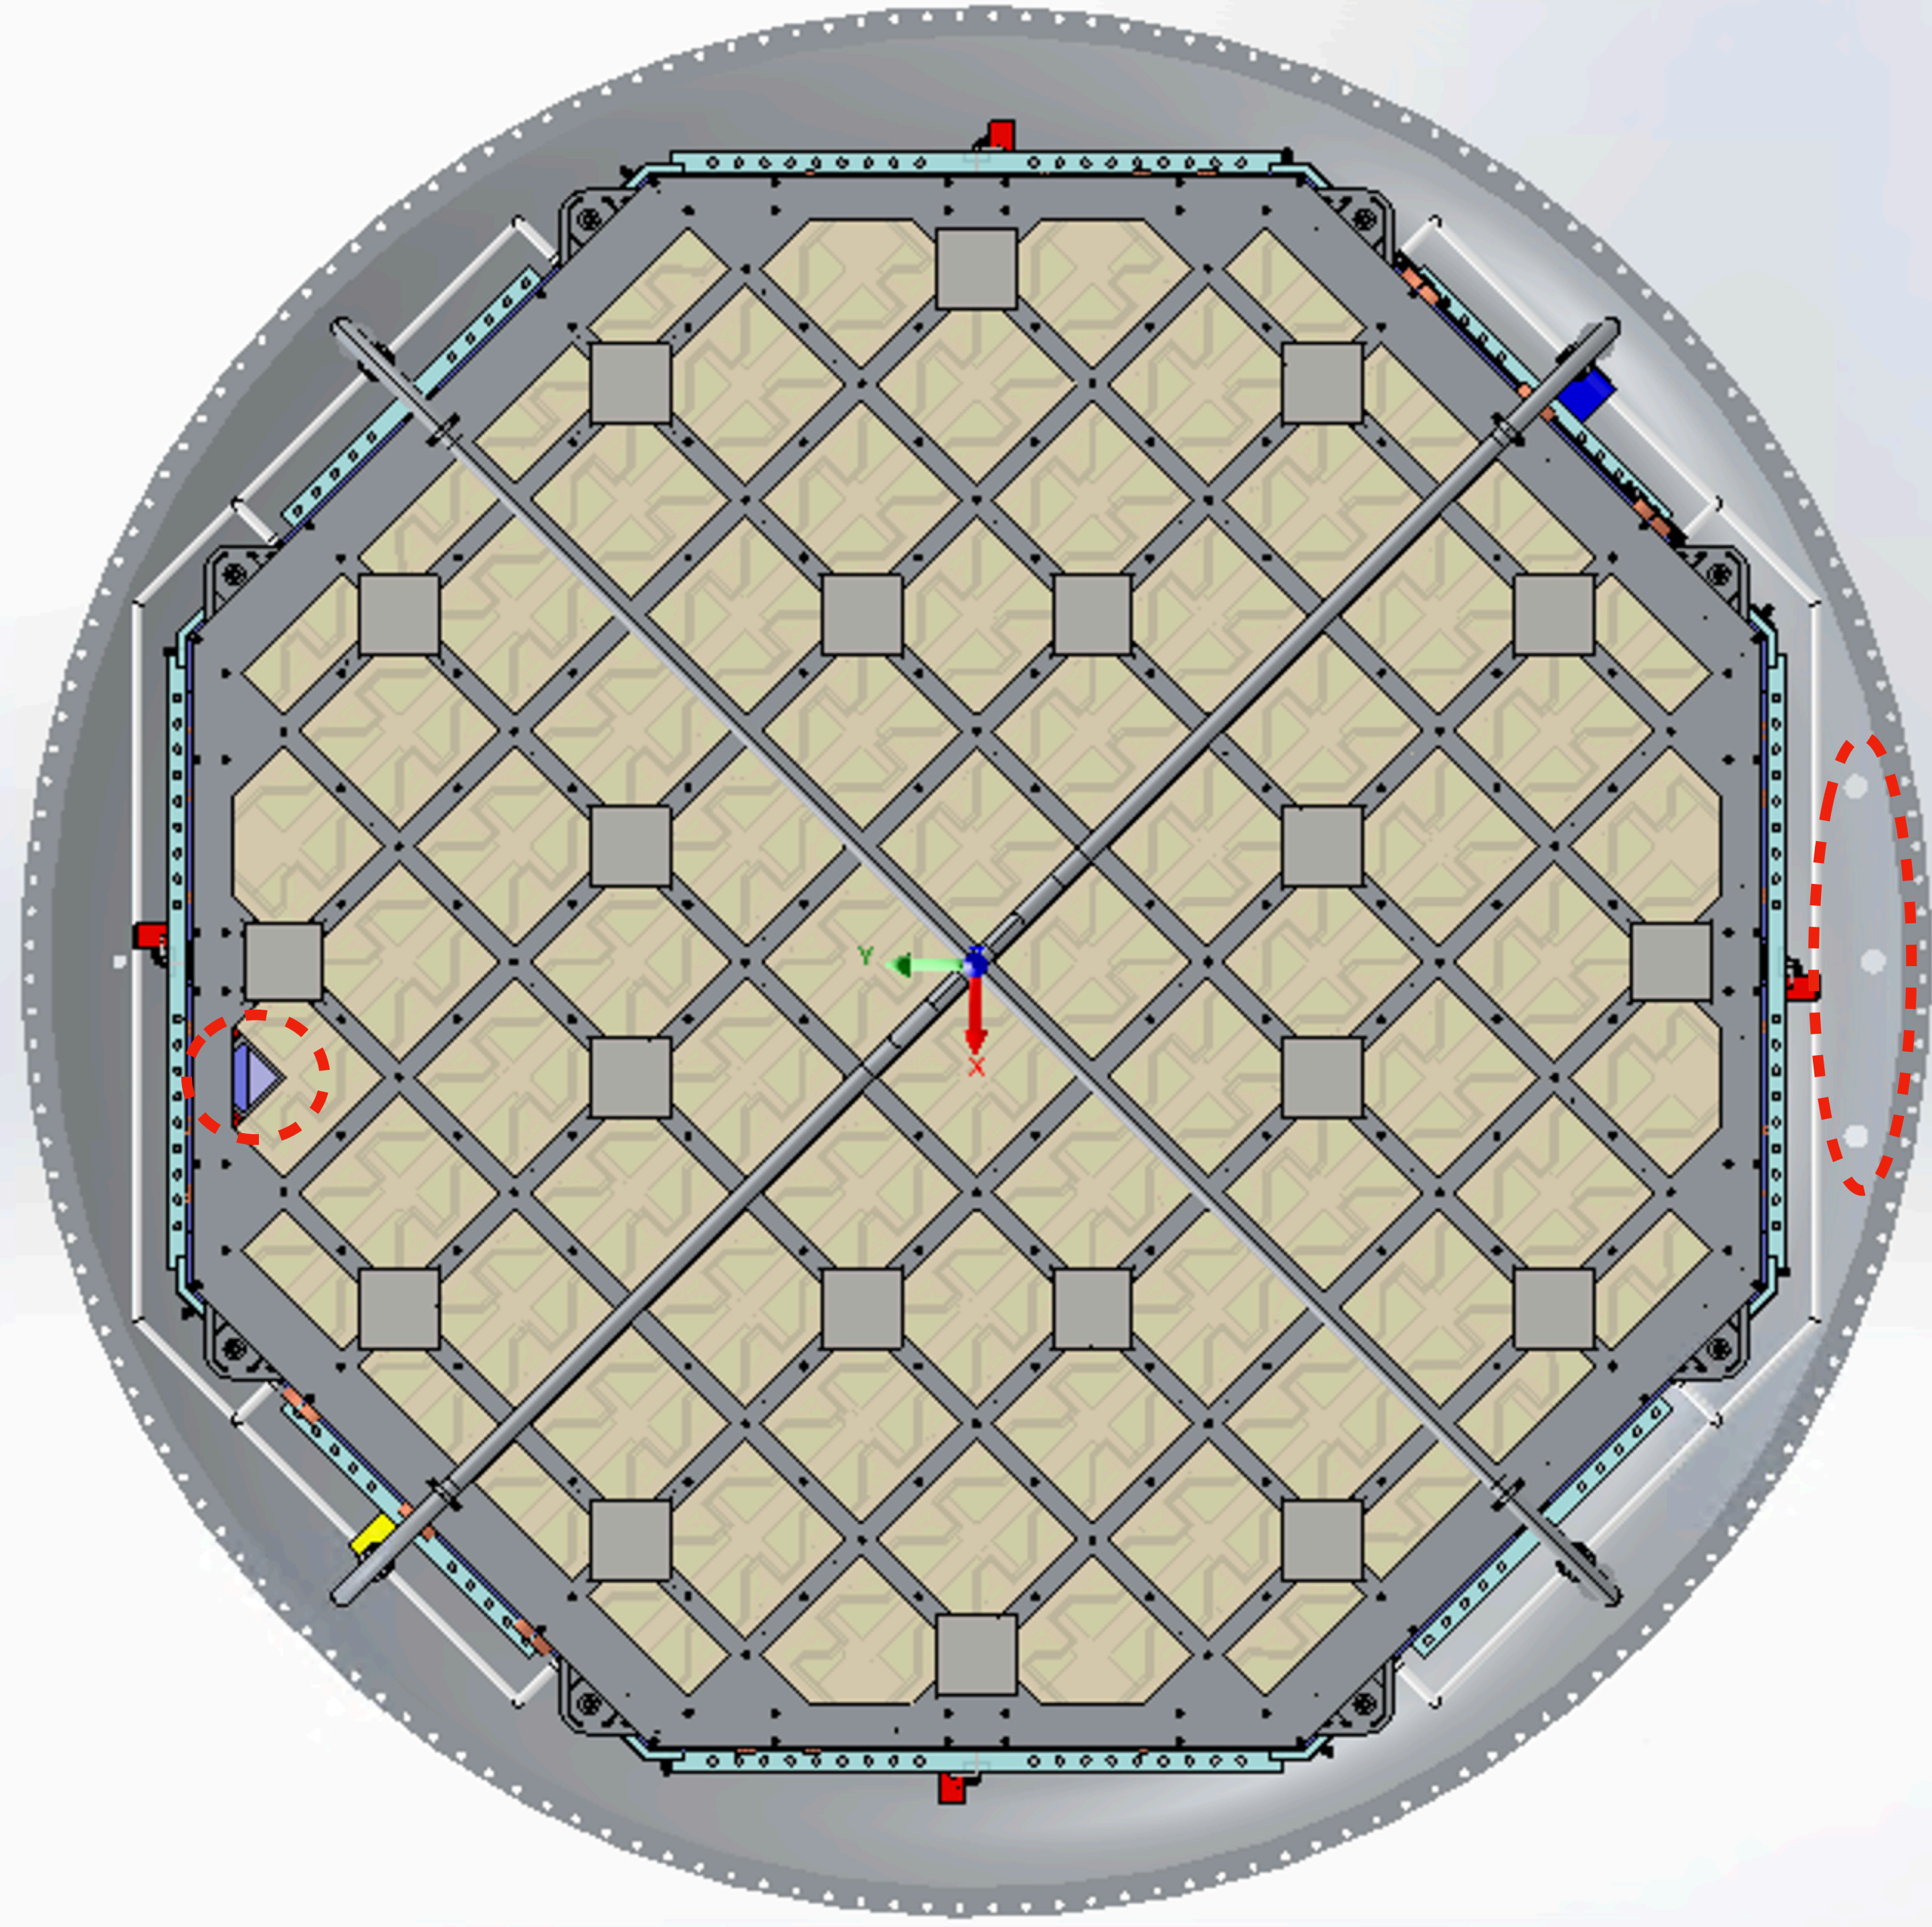

Started bottom-up knowing the vessel dome orientation is fully defined by matching of HV ports on the cryostat;

1. **BOP** orientation **fully defined** by HV cone (opposite side of dome HV ports);
 - ➡ *No conflicts between vPDU and CAL pipes;*
 - ➡ *Optimum alignment between potential cable bundle location and dome cable ports.*
2. **CATHODE** orientation **fully defined** by HV cone (opposite side of dome HV ports);
3. **TOP** has **2 orientations** fulfilling the (weak) requirement that it mirrors BOP as far as cable bundles are concerned;
4. **ANODE** orientation **fully defined** by TOP
 - ➡ *No conflicts between CAL pipes and ANODE levelmeter ports;*
5. **BARREL** has **4 orientations** fulfilling the requirement that the level meters do not conflict with CAL pipes
 - ➡ *Boiler/Bubbler location will follow naturally;*

Side with no cables

Labelling

- Need to find a way to propagate the label (1...8) to object names within the sub-assemblies;
 - ➔ Need to change name of “object” in the tree of each sub-assembly and not of the component file (that is used multiple times within an assembly)
- Luca will reach out to the responsible of the component design to implement this together
 - Anode: Anson
 - Cathode & Barrel: Mitch
 - TOP & BOP: Emile
 - Grid: Tristan
 - Vertical Rods: Emile
