Unveiling SU(3) Flux Tubes At Nonzero Temperature: Electric Fields and Magnetic Currents

M. Baker, V. Chelnokov, L. Cosmai, F. Cuteri, and A. Papa,
Eur.Phys.J.C 84 (2024) 2, 150, [arXiv:2310.04298]

Investigation of deconfinement in SU(3) pure gauge theory at finite temperature.

The transverse profile of the nonperturbative chromoelectric field produced by a static quark-antiquark pair.

Observed the breakdown of the nonperturbative chromoelectric field created by a static quark-antiquark pair as temperature rises: a signal for color deconfinement.

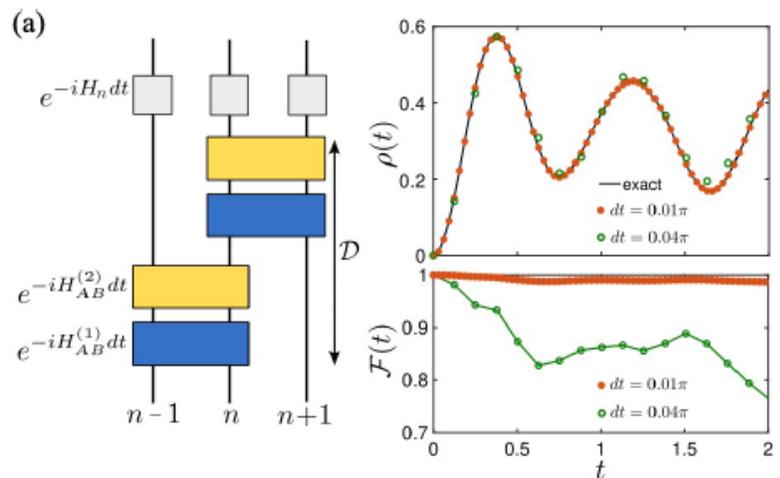

The QCD Vacuum as a Disordered Chromomagnetic Condensate

Paolo Cea, *Universe* 10 (2024) no.3, 111 [arXiv:2311.14791]

- An attempt is made to describe from first principles the *large-scale structure of the confining vacuum in quantum chromodynamics*.
- It has been show that the SU(3) vacuum in three-space and one-time dimensions behaves like a *disordered chromomagnetic condensate*.
- *Color confinement* is assured by the presence of a *mass gap* together with the *absence of color long-range correlations*.
- We offer a clear physical picture for the formation of the flux tube between static quark charges that allows us to determine the *color structure and the transverse profile of the flux-tube chromoelectric field*. The transverse profile of the flux-tube chromoelectric field turns out to be in reasonable agreement with lattice data.
- We, also, show that our quantum vacuum allows for both the color and ordinary Meissner effect. We find that *for massless quarks, the quantum vacuum can accommodate a finite non-zero density of fermion zero modes leading to the dynamical breaking of the chiral symmetry*.

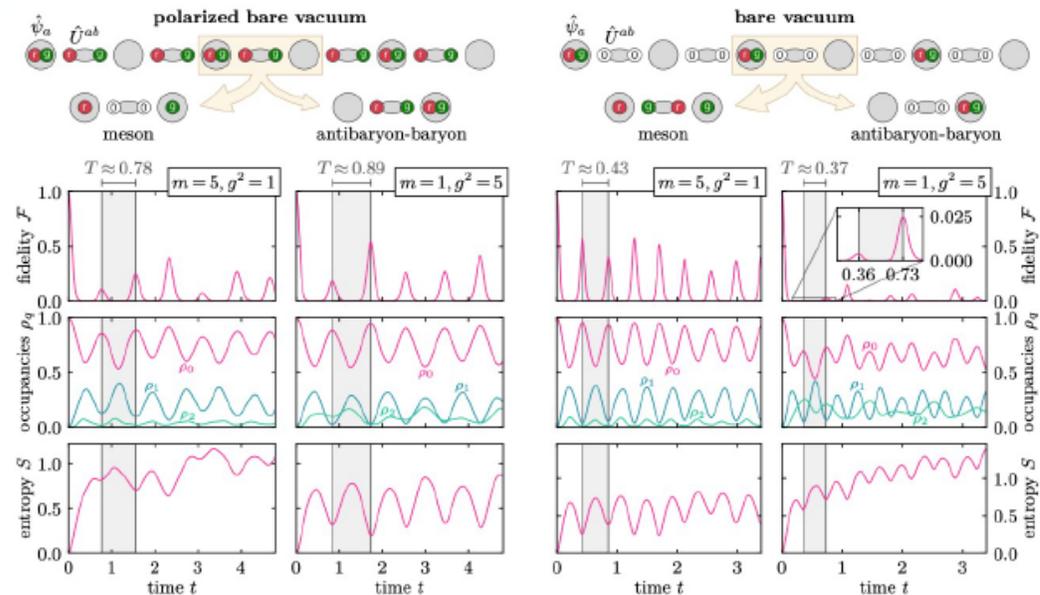

NPQCD: Quantum simulation of a (1+1)D SU(2) LGTs and many-body scar states

G. Calajò, G. Magnifico, C. Edmunds, M. Ringbauer, S. Montangero, P. Silvi, arXiv:2402.07987

- We present a **quantum simulation** strategy for a (1+1)D SU(2) non-abelian lattice gauge theory tailored to trapped-ion **qudit quantum processor**.
- We illustrate how a shallow circuit with these resources is sufficient to implement scalable digital quantum simulation of **the dynamics of the model**.
- We also numerically show that this model, albeit simple, can dynamically manifest physically-relevant properties specific to non-abelian field theories, such as **baryon excitations**.

G. Calajò, G. Cataldi, M. Rigobello, D. Wanisch, G. Magnifico, P. Silvi, S. Montangero, Jad C. Halimeh, arXiv:2405.13112

- Quantum many-body scarring (QMBS) is an intriguing mechanism of ergodicity breaking. Particularly prominent in Abelian lattice gauge theories (LGTs), an open question is whether QMBS nontrivially arises in non-Abelian LGTs.
- For the first time, we present evidence of robust quantum many-body **scar states** and **absence of thermalization** in a non-Abelian SU(2) LGT with dynamical matter.

(Received 14 October 2023; revised 13 March 2024; accepted 14 March 2024; published 2 April 2024)

We leverage recent advances in information theory to develop a method to characterize the dominant character of the high-order dependencies of quantum systems. To this end, we introduce the *Q-information*: an information-theoretic measure capable of distinguishing quantum states dominated by synergy or redundancy. We illustrate the measure by investigating the properties of paradigmatic entangled qubit states and find that—in contrast to classical systems—quantum systems need at least four variables to exhibit high-order properties. Furthermore, our results reveal that unitary evolution can radically affect the internal information organization in a way that strongly depends on the corresponding Hamiltonian. Overall, the *Q-information* sheds light on aspects of the internal organization of quantum systems and their time evolution, opening different avenues for studying several quantum phenomena and related technologies.

Spontaneous self-constraint in active nematic flows

Received: 8 June 2023
Accepted: 14 November 2023
Published online: 18 January 2024

Louise C. Head¹, Claire Doré^{2,3}, Ryan R. Keogh¹, Lasse Bonn⁴, Giuseppe Negro⁵, Davide Marenduzzo¹, Amin Doostmohammadi⁶, Kristian Thijssen⁶, Teresa López-León⁶ & Tyler N. Shendruk^{1*}

Active processes drive biological dynamics across various scales and include subcellular cytoskeletal remodelling, tissue development in embryogenesis and the population-level expansion of bacterial colonies. In each of these, biological functionality requires collective flows to occur while self-organised structures are protected. However, the mechanisms by which active flows can spontaneously constrain their dynamics to preserve structure are not known. Here, by studying collective flows and defect dynamics in active nematic films, we demonstrate the existence of a self-constraint, namely a two-way, spontaneously arising relationship between activity-driven isosurfaces of flow boundaries and mesoscale nematic structures. We show that self-motile defects are tightly constrained to viscometric surfaces, which are contours along which the vorticity and the strain rate are balanced. This in turn reveals that self-motile defects break mirror symmetry when they move along a single viscometric surface. This is explained by an interdependence between viscometric surfaces and bend walls, which are elongated narrow kinks in the orientation field. These findings indicate that defects cannot be treated as solitary points. Instead, their associated mesoscale deformations are key to the steady-state coupling to hydrodynamic flows. This mesoscale cross-field self-constraint offers a framework for tackling complex three-dimensional active turbulence, designing dynamic control into biomimetic materials and understanding how biological systems can employ active stress for dynamic self-organisation.

Non-equilibrium statistical systems and fluids (FieldTurb)

Topology constrains the number of singularities of a vector field on a closed surface. This is also relevant for active nematic droplets, where protein filaments convert chemical energy in local movement of the filaments, that under proper conditions can give rise to coherent motion of the droplet. In this picture we have two standard fluid bubbles immersed in an active nematic droplet. The line corresponds to a topological defect loop, where differently colored segments correspond to a different local defect charge, acting as a rotor as highlighted by the velocity field (colored arrows)

G. Negro and G. Gonnella under review Nat. Com. 2024, L. Head, G. Negro et al. Nat. Phys. 2024

In this work we show how the phase diagram of Lennard Jones particles is changed by the presence of chiral interactions, where neighboring particles rotate one with respect to the other. This configuration taken from numerical simulations performed on ReCas and Cineca, show the presence of domains of different orientation, together with the presence of velocity currents on the boundaries of the domains

C. Caporusso & G. Gonnella PRL 2024

These kind of models are relevant as examples of **non equilibrium systems**, with potential applications in drug delivery
