# Several femtoscopy measurements by ALICE at the LHC

- ALICE experiment has provided unprecedented precise input for the study of hadronic interactions

## List of ALICE femtoscopy measurements

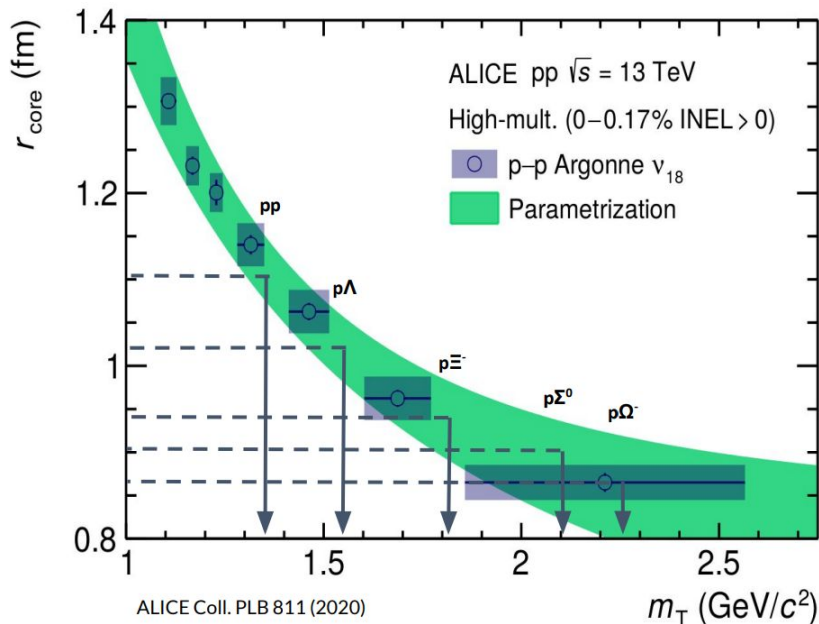

■ baryon-baryon  
■ meson-meson  
■ meson-baryon  
■ Three-body systems

# Source determination

- Small particle-emitting source created in pp collisions at the LHC
- Source size provide information on the scale of the interaction region
- Constrain source with common  $m_T$  scaling

# Source determination

- The emitting source function used to describe the p-p correlation function

$$C(k^*) = \int S(\vec{r}) |\psi(\vec{k}^*, \vec{r})|^2 d^3\vec{r}$$

measured known interaction

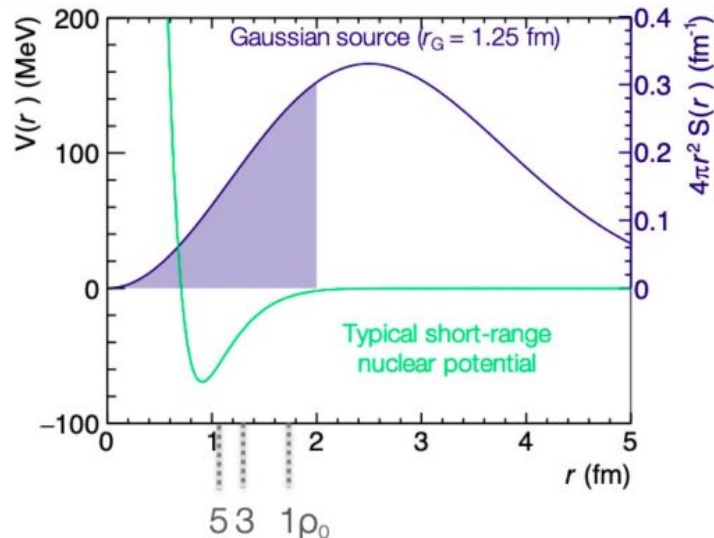

- The **source function** is parameterised by the **gaussian parameterization**

$$S(r) = \frac{1}{(4\pi r_{core}^2)^{3/2}} \exp\left(-\frac{r^2}{4r_{core}^2}\right) \times \text{Effect of short lived resonances } (c\tau \sim 1 \text{ fm})$$

- Small particle-emitting source created in pp collisions at the LHC

*ALICE Coll., PLB, 811(2020, 135849), ALICE Coll., arXiv:2311.14527*

- One global source for all hadrons**

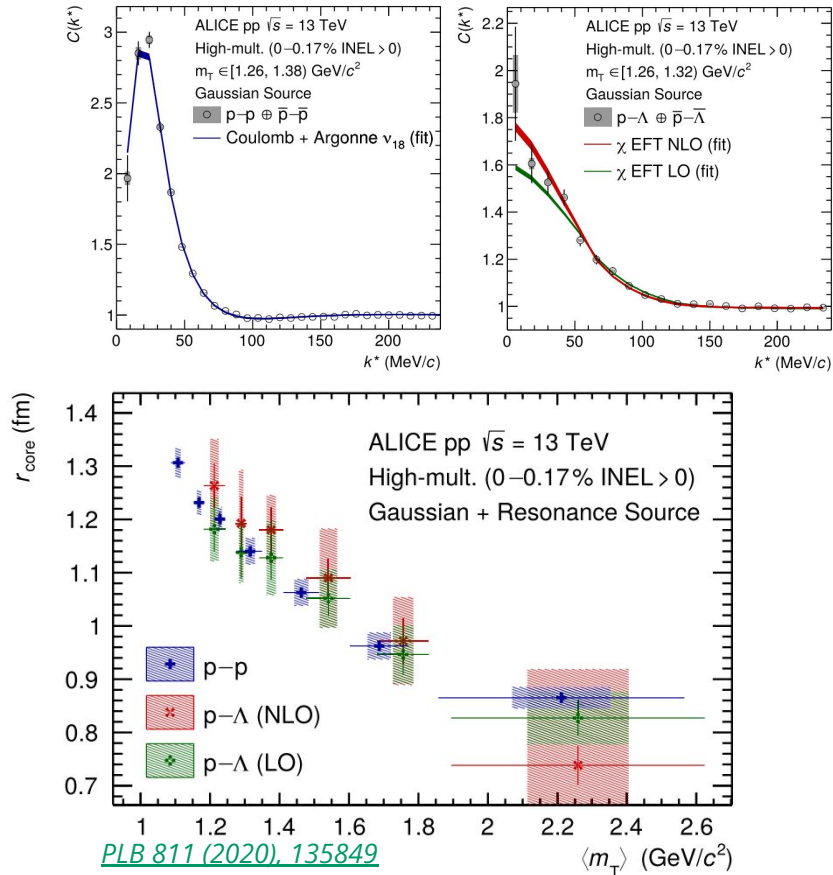

# p-p source in pp collisions in ALICE at the LHC

- Gaussian source used to study the p-p and p- $\Lambda$  source size
- Argonne AV18 + Coulomb potentials used to calculate the two particle wave function
- Two particle wave function as solution to Schrodinger's equation  
→ by using **CATS** (Correlation Analysis Tool using the Schrodinger equation) framework

# Source measurement in pp collisions in ALICE at the LHC

- Gaussian source used to study the p-p and p- $\Lambda$  source size
- Observed to follow  $m_T$  scaling
- Different source size (core radius) for different species
- Here, an assumption is made that the Gaussian “primordial core” is common for all the species but modifies from short lived hadronic resonances.
  - protons ( $\frac{2}{3}$  fraction of all) comes from resonance decay ( $\Delta$ , heavier- $\Delta$ ,  $N^*$ ,  $\Lambda$  resonances)
  - similarly,  $\Lambda$  comes from resonance decay (prominently via  $\Sigma$  resonances, heavier- $\Delta$ ,  $N^*$ ,  $\Sigma$  resonances)

# Common baryon source in pp collisions

- Gaussian source used to study the p-p and p- $\Lambda$  source size
- Observed to follow  $m_T$  scaling
- Different source size (core radius) for different species
- Any baryon pair should follow this  $m_T$  scaling
  - source size can be extracted based on the  $m_T$  of the measured pairs
  - way to allow for precisely studying the strong interactions

# Universal source for all the hadrons

<https://arxiv.org/pdf/2004.08018>  
accepted by EPJC

- Gaussian core radius ( $r_{\text{core}}$ ) results for protons, pions and kaon-proton pairs in High-multiplicity pp collisions at 13 TeV
- Remarkable agreement of  $r_{\text{core}}$  for meson-meson and meson-baryon pairs with the  $m_{\text{T}}$  scaling of the source size.
- Additional support for the scenario of a common emitting source for all hadrons in small system

# Source measurement in pp collisions in ALICE - RUN3

- Recent RUN3 results at pp collisions at 13.6 TeV
- Study multiplicity dependence
- Observed  $m_T$  scaling

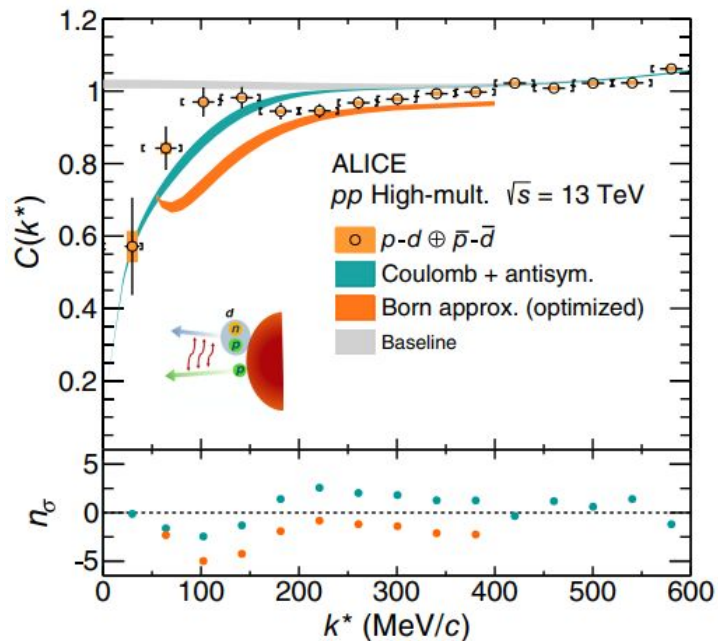

# p-d correlation in pp collisions in ALICE at the LHC

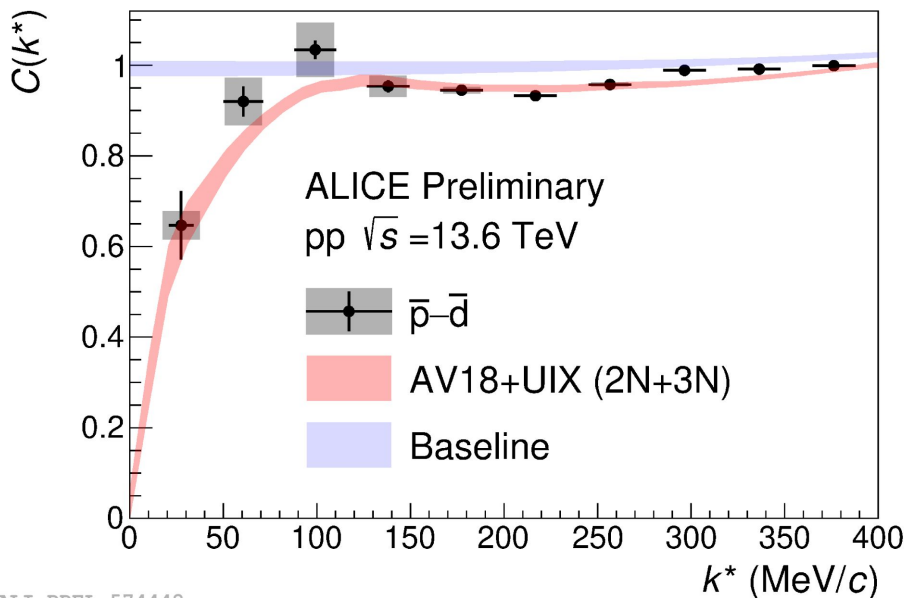

- P-d as an effective two-body  
→ used LL approach
- Source size =  $1.08 \pm 0.06$  fm
- Strong interaction is constrained from scattering measurements
- Picture of two-point like particle does not work
- Need of three-body calculations accounting for p-pn dynamics

# p-d correlation in pp collisions in ALICE at the LHC

- Deuteron treated as composite object, only full three-body calculation accounts for internal structure of deuteron can explain the data (Av18-NN + Urbana IX-NNN + Quantum statistics)
- The argonne AV18 potential is used for the calculation, 5% uncertainty to three-body forces
- Hadron-nuclei correlations at the LHC can be used to study many-body dynamics

# p-d correlation in pp collisions in ALICE - RUN3

ALI-PREL-574442

- Only full three-body calculation accounts for internal structure of deuteron can explain the data (NN + NNN + Quantum statistics)
- Analysed Run3 data at 13.6 TeV, promising results, possibility of  $m_T$ -differential analysis
- Expected uncertainty to three-body forces upto 1%

# p- $\Lambda$ correlation in pp collisions in ALICE at the LHC

- Gaussian source (modelled by CATS) with chiral magnetic field theory potentials
- Sensitive to different  $\Sigma N$  coupling strength
- Next to leading order (NLO19) is favoured within  $n_\sigma = 3.2$
- Attractive interaction of  $\Lambda$  at large density

# K-d correlation in pp collisions in ALICE at the LHC

- K-d as an effective two-body system by using LL approach
- Source size =  $1.35 + 0.04 - 0.05$  fm
- First measurement in pp collisions
- Deuterons are produced in shorter distances together with hadrons

# Source size increases with increasing multiplicity

- Attempt of multiplicity dependent source size measurement
- Innovative behaviour of growing  $r_{\text{core}}$  with increasing multiplicity
- Scaling of  $r_{\text{core}}$  with increasing  $m_T$
- Saturation of source size below 600 MeV/c<sup>2</sup>
