- Conclusions

## The Standard Model of particles and fields

#### See previous talk by Fulvio Piccininni

- The Standard Model (SM) of particle physics is a well-established theory that describes the fundamental particles quarks, leptons, and gauge bosons, and their interactions via the electromagnetic, weak, and strong forces. The Higgs field is a pervasive field that interacts with the SM elementary particles. As a consequence of this interacation, the particles acquire mass. The Higgs boson is the "quantum" particle associated to this field.
- With the discovery of the **Higgs boson** in 2012, the **Standard Model** of particle physics is validated as the **most complete and** accurate theoretical description of the known fundamental particles and their interactions.
  - The Higgs boson was the last missing piece of the SM, and its discovery at CERN's Large Hadron Collider (LHC) was a triumph, confirming the existence of the Higgs field.

Standard Model of Elementary Particles

## Future Colliders

- Future Colliders are essential for addressing the most pressing unanswered questions in the Standard Model and beyond. Two basic paths:
  - **Precision Physics**: Precision measurements are critical for testing the Standard Model's predictions and searching for subtle deviations that may indicate new physics. Key examples:
    - **Higgs Sector:** <u>Higgs boson couplings</u> accurate measurements; understanding the Higgs potential through <u>self-coupling</u> studies to explore electroweak symmetry breaking.
    - more accurate measurements of particle properties (e.g., masses, lifetimes, and couplings) and particle production cross sections
  - Search for new objects and new phenomena: Searching for new particles and phenomena is the primary way to uncover physics beyond the Standard Model. Examples:
    - Dark Matter Candidates
    - New Gauge Bosons (Z' or W')
    - Exotic Phenomena
    - Anomaly Detection

# Future Colliders

#### • Approved Future Colliders:

- High-Luminosity LHC, HL-LHC, at CERN 0
- High-luminosity SuperKEKB (focused on flavor physics, CP violation, and rare decays)
- EIC e<sup>-</sup>p/n collider, BNL

#### • Most prominent proposed New Colliders:

- FCC: FCC-ee followed by FCC-hh, at CERN
- Linear e<sup>+</sup>e<sup>-</sup> Collider, in Japan, or at CERN
- **Muon Collider** (in USA??)
- CepC (followed by CppC), in China
- CCC (also known as C3) in USA
- Plasma-based linear e<sup>+</sup>e<sup>-</sup> collider, at DESY

# The LHC luminosity upgrade: HL-LHC

#### **Main HL-LHC targets**

- A peak luminosity of  $L_{peak} = 5 \times 10^{34} \text{ cm}^{-2} \text{s}^{-1}$  with levelling
- An integrated luminosity of **250 fb<sup>-1</sup> per year per ATLAS/CMS**, enabling the goal of
- L<sub>int</sub> = 3000 fb<sup>-1</sup> twelve years after the upgrade, per ATLAS/CMS.

This luminosity is **more than ten times** the luminosity reach of the first 10 years of the LHC lifetime.

• furthermore:...  $\sqrt{s} = 14 \text{ TeV}$ 

**Ultimate performance** established 2015-2016: with same hardware and same beam parameters: use of **engineering margins:**  $L_{peak ult} \cong 7.5 \ 10^{34} \ cm^{-2} s^{-1}$  and **Ultimate Integrated**  $L_{int ult} \sim 4000 \ fb^{-1}$ LHC should not be the limit, would Physics require more

- → > 1 year until start of Long Shutdown 3 [postponed to 29 June 2026]
- → > 80% of the project budget of 1.1 BCHF already committed
- → The project is ready for LS3 installation start in 2<sup>nd</sup> half of 2026!

#### **Challenge: Pileup** Number of events in pile up: 140, up to 200

pileup

High pileup environment at the HL-LHC brings new challenges: detector irradiation, higher detector occupancy, higher trigger rates

Elizabeth Brost - Higgs@10 Symposium - July 4th, 2022

### HL-LHC ATLAS, CMS and LHCb detector upgrade

8

- HL-LHC: the most powerful tool to address these major challenges to our fundamental understanding of nature
- Detectors must be designed to fully exploit the physics potential of the HL-LHC while withstanding the demanding environmental conditions in which they are expected to operate

# Higgs couplings @ HL-LHC

- **Precision Higgs coupling measurement at HL-LHC**
- Precision on couplings to  $\gamma$ , W, Z and  $\tau$ < 2 %</th>Precision on couplings to g, t, b and  $\mu$ < 5 %</td>Precision on couplings to  $Z\gamma$ < 10 %</td>
- Many projections show limitation from theory Uncertainties (despite the assumptions made)
- The study was and it still is fundamental for:
- The European Strategy for Particle Physics Update 2019-2020
- The Particle Physics Project Prioritization Panel (P5) in USA, 2023
- The European Strategy for Particle Physics Update 2026
- P5 Processes in USA

### Future Colliders: e<sup>+</sup>e<sup>-</sup> (/lepton) Higgs Factories

11

- Higgs production at e+e- colliders:  $e^+e^- \rightarrow ZH$ ,  $\nu\nu H$ ,  $e^+e^-H$
- precisely known initial state: the beam particles are elementary, the colliding particles initial state is  $\mathbf{P_i} = (1/2 \cdot \sqrt{s}; 0; 0; 1/2 \cdot \sqrt{s})$
- The process  $e^+e^-$  colliders:  $e^+e^- \rightarrow$  ZH is very clean, the Z can be easily detected and reconstructed thanks to the leptonic decays
- Momentum and energy conservation allow the reconstruction of the "recoil mass"

$$M_{rec}^{2} = (\sqrt{s} - E_{l+l-})^{2} - |\mathbf{P}_{l+l-}|^{2} = s - M_{l+l-}^{2} - 2 \cdot E_{l+l-} \cdot \sqrt{s}$$
  
M<sub>rec</sub> is the **recoil mass**

### extraction of the $g_{ZZ}$ Higgs boson coupling - natural width $\Gamma_{H}$

events / 0.50 Ge/

Improved-Born Higgs production cross section (with initial state radiation included) as a function of  $\sqrt{s}$ . M<sub>H</sub> set to 125 GeV.

13

Inclusive mrecoil distribution for events with a Z decaying to  $\mu + \mu -$  in the mass region  $40 \div 160$  GeV.

- Higgs Factory: we can produce  $0.2 \times 10^6$  Higgs boson per 1 ab<sup>-1</sup> (*a*)  $\sqrt{s} = 240$  GeV
- The measurement of the ZH production cross section gives access to  $g_{HZZ}^2$ :  $\sigma(e^+e^- \rightarrow ZH) \propto g_{HZZ}^2$  (no analysis of the Higgs boson decays)
- Higgs boson partial width:  $\Gamma(\text{HZZ})$  is also proportional to  $g_{\text{HZZ}}^2$
- Including Higgs boson decays, and considering other Higgs boson production processes, we can extract  $\Gamma_{\rm H}$  and of all other Higgs boson couplings in a model independent way (this is not possible at hadron colliders)

### FCC: a new accelerator facility at CERN for future

- The fundamental concept of the FCC project is to establish a new facility at CERN, designed to deliver a comprehensive and extensive scientific programme aimed at addressing the most significant open questions in fundamental physics, through complementary physics initiatives based on particle accelerators.
  - Priorities are set on the base of scientific arguments and machine&detector feasibility
- The most effective plan we can devise is an infrastructure capable of accommodating high-intensity and high-energy future colliders with multiple particle beams.
- A circular collider is the best solution to develop such a project
  - This needs the construction of a new, large tunnel in the CERN region
  - This tunnel can host in an initial phase an e+e- collider to allow the study of the electroweak and Higgs sectors of the Standard Model
  - Subsequently, this tunnel can host a very high energy p-p collider to allow searches at the energy frontier of new particles and new phenomena beyond Standard Model
  - Moreover, this facility can be used also for other complementary frontier physics investigations, installing an electron-proton collider, a muon collider(?) or an ion collider(?)

### **FCC integrated program**

#### comprehensive long-term program maximizing physics opportunities

- stage 1: FCC-ee (Z, W, H, tt) as Higgs factory, electroweak & top factory at highest luminosities
- stage 2: FCC-hh (~100 TeV) as natural continuation at energy frontier, pp & AA collisions; e-h option
- highly synergetic and complementary programme boosting the physics reach of both colliders
- common civil engineering and technical infrastructures, building on and reusing CERN's existing infrastructure
- FCC integrated project allows the start of a new, major facility at CERN within a few years of the end of HL-LHC

FCC Feasibility Study Status Michael Benedikt 2<sup>nd</sup> FCC Italy & France WS, 4 November 2024

#### Reference layout and implementation: PA31 - 90.7 km

Layout chosen out of ~ 100 initial variants, based on **geology** and **surface constraints** (land availability, access to roads, etc.), **environment,** (protected zones), **infrastructure** (water, electricity, transport), **machine performance** etc.

"Avoid-reduce-compensate" principle of EU and French regulations

Overall lowest-risk baseline: 90.7 km ring, 8 surface points, 4-fold symmetry

#### **FCC-ee main machine parameters**

Parameter	Z	ww	Н (ZH)	ttbar
beam energy [GeV]	45.6	80	120	182.5

**Design and parameters to** maximise luminosity at all working points:

- allow for 50 MW synchrotron radiation per beam.
- Independent vacuum systems for electrons and positrons
- full energy booster ring with top-up injection, collider permanent in collision mode

□ x 10-50 improvements on all EW observables

up to x 10 improvement on Higgs coupling (model-indep.) measurements over HL-LHC

LEP x 10<sup>5</sup>

- x10 Belle II statistics for b, c, T
- $\Box$  indirect discovery potential up to ~ 70 TeV
- direct discovery potential for feebly-interacting particles over 5-100 GeV mass range

Up to 4 interaction points  $\rightarrow$  robustness, statistics, possibility of specialised detectors to maximise physics output

# FCC timeline

#### 1<sup>st</sup> stage collider, FCC-ee:

- e+e- collisions 90-360 GeV, Construction: 2033-2045  $\rightarrow$  Physics operation: 2048-2063
- Highest luminosities at Z, W, ZH of all proposed Higgs and EW factories; indirect discovery potential up to ~ 70 TeV

#### 2<sup>nd</sup> stage collider, FCC-hh:

- pp collisions at ~ 100 TeV, Construction: 2058-2070 → Physics operation: ~ 2070-2095
- direct exploration of next energy frontier (~ x10 LHC) and unparalleled measurements of low-rate and "heavy" Higgs couplings (ttH, HH)

Italian community strongly involved

### **FCC-ee Physics Programme**

# Higgs boson couplings at FCC-ee

Coupling	HL-LHC	FCC-ee $(240-365  \text{GeV})$ 2 IPs / 4 IPs
$\kappa_W \; [\%]$	$1.5^{*}$	0.43 / 0.33
$\kappa_Z[\%]$	$1.3^{*}$	0.17 / 0.14
$\kappa_{g}$ [%]	$2^*$	0.90 / 0.77
$\kappa_{\gamma}$ [%]	$1.6^{*}$	1.3 / 1.2
$\kappa_{Z\gamma}$ [%]	$10^{*}$	10 / 10
$\kappa_c$ [%]	—	1.3 / 1.1
$\kappa_t  [\%]$	$3.2^{*}$	3.1 / 3.1
$\kappa_b$ [%]	$2.5^*$	$0.64 \ / \ 0.56$
$\kappa_{\mu}$ [%]	$4.4^{*}$	3.9 / 3.7
$\kappa_{ au}$ [%]	$1.6^{*}$	$0.66 \ / \ 0.55$
$BR_{inv}$ (<%, 95% CL)	$1.9^{*}$	0.20 / 0.15
$BR_{unt}$ (<%, 95% CL)	$4^*$	1.0 / 0.88

Expected 68% CL relative precision (%) of the  $\kappa$  parameters at HL-LHC and FCC-ee (combined with HL-LHC).

- corresponding 95%CL upper limits on the untagged, BRunt, and invisible, BRinv, branching ratios are also given.
- HL-LHC case (\*):  $|\kappa_V| \le 1$  imposed

- Take away conclusion:
  - Higgs couplings at HL-LHC: accuracy in the order of few  $10^{-2}$
  - Higgs couplings at FCC-ee: accuracy in the order of ~  $10^{-3}$  to  $10^{-2}$
- Furthermore:
  - Higgs self-coupling  $g_{HHH}$  can be extracted with an accuracy of 33% (2 IPs) or 24% (4 IPs) studying quantum corrections to single Higgs couplings
  - Higgs boson mass measurement accuracy @ FCC-ee: < 10 MeV

### Direct New Physics searches at FCC-ee: an example

Projected sensitivity (yellow area) for ALPs in the photon coupling versus ALP mass plane from  $e+e- \rightarrow \gamma a \rightarrow 3\gamma$  and photon-fusion  $\gamma\gamma \rightarrow a \rightarrow 2\gamma$  processes at FCC-ee

- Despite the LHC's exploration of energy scales up to O(1) TeV and beyond, FCC-ee can still probe new physics through precision and rare processes, enabling direct searches for weakly coupled particles
- An example is such as **axions** via their decays into photons  $(\mathbf{a} \rightarrow \gamma \gamma)$ , as well as other signatures that may have been challenging to detect in the high-background environment of hadron colliders
- In this case intensity (i.e. high luminosity particle colliders) is key.

## Precision EW measurements

Observable	present	FCC-ee	FCC-ee	Comment and
	value $\pm \text{ error}$	Stat.	Syst.	leading exp. error
$m_{\rm Z}  (\rm keV)$	$91186700 \pm 2200$	4	100	From Z line shape scan

With FCC-hh after FCC-ee: significant amount of time for high-field magnet R&D, aiming at highest possible collision energies

Target field range for cryomagnet R&D

Formidable challenges:

- □ high-field superconducting magnets: 14 20 T
- $\Box$  power load in arcs from synchrotron radiation: 4 MW  $\rightarrow$  cryogenics, vacuum
- □ stored beam energy: ~ 9 GJ  $\rightarrow$  machine protection
- □ pile-up in the detectors: ~1000 events/xing
- $\Box$  optimization of energy consumption:  $\rightarrow$  R&D on cryo, HTS, beam current, ...

Formidable physics reach, including:

- □ Direct discovery potential up to ~ 40 TeV
- Measurement of Higgs self to ~ 5% and ttH to ~ 1%
- High-precision and model-indep (with FCC-ee input) measurements of rare Higgs decays (γγ, Ζγ, μμ)
- □ Final word about WIMP dark matter

F. Gianotti

# FCC-hh: Higgs boson self-coupling

FCC integrated is expected to measure the Higgs selfcoupling with an accuracy of a very few %!

#### The main challenges for FCC-hh • The accelerator: High-field

- The accelerator: High-field Magnets
  - LHC dipole field: 8.33 T (technology: NbTi)
- Two avenues:
  - Nb<sub>3</sub>Sn: operational field: 14 T (~4 K?)
  - High-Temperature Superconducting magnets (HTS; example REBCO): ~ 20 T (~ 20 K)

• The Detector, Trigger, DAQ, offline computing...:

main FCC-hh Detector challenges:

26

- Radiation hardness
- Large rapidity coverage
- High-granularity
- 4D detection

•

### Alternatives to electron-positron circular colliders

• Because their small mass, electrons loose energy when experiencing large acceleration

• Larmor formula: 
$$P = \frac{e^2 c}{6\pi\varepsilon_0 R^2} \left(\frac{E}{mc^2}\right)^4$$

*e* is the elementary charge  $(1.602 \times 10^{-19} \text{ C})$ *m* is the electron mass  $(9.1093837 \times 10^{-31} \text{ kg})$ c is the speed of light  $(3.00 \times 10^8 \text{ m/s})$  $\varepsilon_0$  is the vacuum permittivity  $(8.854 \times 10^{-12} \text{ F/m})$ *R* is the radius of curvature of the orbit, in m.

- If we set the beam Energy *E*, the synchrotron energy power dissipation per electron depends only by the radius of the orbit *R*
- The only way to limit the synchrotron energy loss of electron beams of circular colliders is to build large R accelerators
  - o if we put FCC-ee the electron/positron beam parameters, we get 50 MW power per beam
  - an FCC twice smaller would imply a synchrotron radiation power loss of 200 MW per beam!!
- For many years, we considered only one alternative: **linear colliders** • these offer beam polarisation as well
- Now the community proposes to accelerate and collide muon beams at the place of electron beams → the Muon Collider

# Muon Collider

- This is a revolutionary idea!!
- But several challenges are ahead of us, due to two basic facts:
- 1. Muons are produced with large emittance
  - Here I assume hadron production of muons, as opposed to lepton production
- 2. Muons are unstable:  $\tau_{\mu} = 2.2 \ \mu s$ 
  - They decays most of the time in electrons and neutrinos  $\mu^{\pm} \rightarrow e^{\pm} \nu_{\mu} \nu_{e}$
- This means that  $\rightarrow$
- 1. We need to **cool muon beams** before they collide
- 2. The sequence injection  $\rightarrow$  cooling  $\rightarrow$  acceleration  $\rightarrow$  collision must occur in a very short time! (fraction of a second!):  $\tau_{\mu}^{\text{lab}} = \tau_{\mu} \cdot \gamma = 0.1 \text{ s}$  for  $E_{\mu} = 5 \text{ TeV}$ 
  - Equivalent time @ LEP: 2 3 hours (electron/positron beams)
  - Equivalent time @ LHC: 20 30 minutes (proton beams)
  - Only a small fraction of muons "survives" till the acceleration phase (O(1-10%))

### Muon Collider Overview

#### **Key Challenges**

#### **Environmental impact**

- Neutrino flux mitigation
- Power, cost, CO<sub>2</sub>, ...

Key technologies for timeline

- Magnet technology
- Muon cooling technology
- Detector

**Other technologies** are instrumental for performance, cost, power consumption and risk mitigation

• Accelerator physics, cryogenics, superconducting cavities, ....

**Beam-induced background** Decay of stored muons around the collider ring is the dominant source. Pair creation through the collision of two real or virtual photons emittedby muons of counter-rotating bunches

Other important timeline considerations are

- Civil engineering
- Decision making

**Cost** and **power** consumption limit energy reach e.g. 35 km accelerator for 10 TeV, 10 km collider ring Also impacts **beam quality** 

#### Daniele Calzolari, Padova Anatomy of decay-induced background

by Davide Zuliani

### Muon Collider Detector

Detector concept at  $\sqrt{S} = 3$  TeV was adapted from the CLICdet

**Strong Italian contribution** 

#### At $\sqrt{S} = 10$ TeV two different detectors are proposed

# Physics at the Muon Collider – Higgs sector

The Muon Collider allows lepton collisions (in this case  $\mu^+\mu^-$ ) at energies much larger than those produced by circular e<sup>+</sup>e<sup>-</sup> colliders

Cross sections for the most important single and double Higgs production modes as a function of energy. Here ZH and ttH are s-channel production while the others are Vector Boson Fusion produced in association with any of  $(\nu_{\mu}\nu_{\mu}, \nu_{\mu} \mu^{\pm}, \mu^{+}\mu^{-})$ .

multi-TeV muon collider is a W<sup>+</sup>W<sup>-</sup> collider cross section [fb] expected events  $1 \text{ ab}^{-1} \text{ at } 3 \text{ TeV}$  $10 \text{ ab}^{-1}$  at 10 TeV 3 TeV 10 TeV  $5.5 \times 10^{5}$  $9.3 \times 10^{6}$ H550 930  $1.1 \times 10^{4}$  $3.5 \times 10^{5}$ ZH11 35  $1.4 \times 10^{3}$ 420 ttH 0.42 0.14  $3.8 \times 10^{4}$ HH0.95 3.8 950 HHH $3.0 \times 10^{-4}$  $4.2 \times 10^{-3}$ 0.30 42

 multi-TeV muon collisions produce significant number of single, double and triple Higgs bosons
 → High-precision Higgs mesaurements including
 highly accurate Higgs self-coupling studies of HH and
 HHH production

### Muon collider options

Parameter	Unit	Higgs Factory	3 TeV	10 TeV
COM Beam Energy	TeV	0.126	3	10
Collider Ring Circumference	km	0.3	4.5	10
Interaction Regions		1	2	2
Est. Integ. Luminosity	ab <sup>-1</sup> /year	0.002	0.4	4
Peak Luminosity	$10^{34} \text{ cm}^{-2} \text{ s}^{-1}$	0.01	1.8	20
Repetition rate	Hz	15	5	5

# Higgs measurements @ the Muon Collider

#### https://arxiv.org/abs/2203.07256

Fig. 5: Left panel:  $1\sigma$  sensitivities (in %) from a 10-parameter fit in the  $\kappa$ -framework at a 10 TeV muon collider with 10 ab<sup>-1</sup> [18], compared with HL-LHC. The effect of measurements from a 250 GeV  $e^+e^-$  Higgs factory is also reported. Right panel: sensitivity to  $\delta\kappa_{\lambda}$  for different  $E_{\rm cm}$ . The luminosity is as in eq. (1) for all energies, apart from  $E_{\rm cm} = 3$  TeV, where doubled luminosity (of 1.8 ab<sup>-1</sup>) is assumed [18].

# European Strategy for Particle Physics

35

- The European Strategy for Particle Physics is a comprehensive framework coordinated by CERN Council to set the priorities and future directions for particle physics research in Europe. It aims to guide scientific, technological, and financial decisions in particle physics, in Europe, but not only: it impacts on a global scale due to the international collaboration and to the impact of CERN/Europe on the fundamental research worldwide.
- This process, typically carried out every 7-8 years, is **based on an extensive consultations with the scientific community, stakeholders, and relevant institutions** to ensure that the strategy reflects the latest scientific and technological advancements and addresses emerging challenges.

#### The update process and its timeline

2024: year of preparation, establishments of committees, choice of locations for the various meetings 2025: submission of scientific inputs, Open Symposium, drafting of the strategic document 2026 discussion at Council and Strategy update (in 2027/2028 Council decides...)

#### Timeline for the update of the **European Strategy for Particle Physics**

#### **Strategy Secretariat:**

organising and running the ESPP process

Strategy Secretary (K. Jakobs.) Paris Sphicas (ECFA Chair) Hugh Montgomery (SPC Chair) Dave Newbold (LDG Chair)

**European Strategy Group (ESG)**: Prepares the Strategy Document

**Physics Preparatory Group** (PPG): collects input from the community, organises the Open Symposium, prepares the Briefing Book

Inputs from the community will be reviewed by **ESG**: careful and rigorous study of the documentation provided, i.e of the Briefing Book drafted by **PPG** with support of the **Strategy Secretariat** Open Symposium 23-27 June 2025 - Lido di Venezia ! I do hope to see you there ..... 36

#### Conclusions

- The Standard Model's success the Higgs boson discovery in 2012 confirmed the Standard Model's robustness. It successfully describes the results produced in laboratories
  - High-precision studies at the LHC continue validating its predictions.
  - The Higgs sector is "new physics" never seen a fundamental scalar so far....
- But the Standard Model is not the final theory: hierarchy problem, Dark Matter, neutrino masses and their oscillations, and matter-antimatter asymmetry remain unexplained. → Need for new physics and possible extensions beyond this theory.
- Future of High-Energy Physics
  - High-Luminosity LHC will refine precision measurements and explore rare processes.
  - **Future colliders** aim to push energy frontiers and uncover new physics.
  - FCC-integrated is the best future project to explore new areas in HEP
  - It is of paramount importance to study revolutionary ideas, e.g. the Muon Collider
- The European Strategy for Particle Physics guides priorities
  - International efforts and technological advancements are key to the next breakthroughs
  - INFN is playing a very important role in the international scenario
- Fundamental physics stands at a crucial moment exciting results, and possible discoveries, lie ahead!

#### Conclusions

• The Standard Model's success - the Higgs boson discovery in 2012 confirmed the Standard Model's robustness. It successfully describes the results produced in laboratories

High precision studies at the I HC continue validating its prediction

#### **Open Symposium on the European Strategy for Particle Physics**

- The European Strategy for Particle Physics guides priorities
  - International efforts and technological advancements are key to the next breakthroughs
  - INFN is playing a very important role in the international scenario
- Fundamental physics stands at a crucial moment exciting results, and possible discoveries, lie ahead!

#### The Higgs Potential

$$\mathcal{L} = T - V = \frac{1}{2} \partial_{\mu} \phi \partial^{\mu} \phi - \left(\frac{1}{2} \mu^{2} \phi^{2} + \frac{1}{4} \lambda \phi^{4}\right)$$

in SM, this potential is fully defined by two parameters, that can be inferred by the v.e.v.  $\nu$  and the Higgs boson mass  $m_h$ 

Expanding around the minimum, 
$$\phi = v + h$$
:  
 $V(h) = \lambda v^2 h^2 + \lambda v h^3 + \frac{1}{4} \lambda h^4 = m_h^2 = 2\lambda v^2$   $\lambda_3 = \lambda v = m_h^2/2v$   
 $\lambda_4 = \lambda/4 = mh^2/8v^2$ 

Higgs boson pair (HH) production allows to probe *directly* the Higgs boson self-interaction and, ultimately, the shape of the Higgs potential.

> ➔Any deviation from the self-interaction predicted by the SM would be a sign of new physics!

V-(#)  $\frac{1}{2}m_h^2h^2 + \lambda_3h^3 + \mu_3h^3 + \mu_3h^3$  $\lambda_4 h^4$ Higgs triple Higgs quartic mass term coupling coupling н Н

#### The discovery of the 125 GeV Higgs boson

#### 4 July 2012

- Summer 2011 EPS and Lepton-Photon: Still focused on limits.

## The Higgs boson - 1

Results of a simultaneous fit for  $\sigma_{ggF}^{ZZ}$ ,  $\sigma_{VBF}/\sigma_{ggF}$ ,  $\sigma_{WH}/\sigma_{ggF}$ ,  $\sigma_{ZH}/\sigma_{ggF}$ ,  $\sigma_{ttH+tH}/\sigma_{ggF}$ ,  $B_{\gamma\gamma}/B_{ZZ}$ ,  $B_{WW}/B_{ZZ}$ ,  $B_{\tau\tau}/B_{ZZ}$ , and  $B_{bb}/B_{ZZ}$ . The fit results are normalized to the SM predictions.

The black error bars, blue boxes and yellow boxes show the total, systematic, and statistical uncertainties in the measurements, respectively. The grey bands show the theory uncertainties in the predictions.

#### These measurements are *model INDEPENDENT* results:

At LHC is not possible to make a model independent extraction of the Higgs boson naturall width  $\Gamma_{\rm H}$ 

**Cross-sections for ggF, VBF, WH, ZH and tfH+tH normalized to their SM predictions, measured with the assumption of SM branching fractions.**  The observed signal strengths and uncertainties for different Higgs boson decay channels and their combination for  $m_H$ =125.36 GeV, with the assumption of SM of cross-section ratios of different production processes.

Higgs boson signals corresponding to the same decay channel are combined together for all analyses

Constraints on the Higgs boson coupling modifiers to fermions ( $\kappa_f$ ) and heavy gauge bosons ( $\kappa_V$ ), in different data sets discovery (red), the full LHC Run 1 (blue), and the data presented here (black).

The SM prediction corresponds to  $\kappa_V = \kappa_f = 1$  (diamond marker). uncertainty of 10%, with the predictions from the SM **Coupling modifiers probed at a level of uncertainty of 10% - except for** 

•  $\kappa_{\rm b}$  and  $\kappa_{\mu}$ :  $\approx 20\%$ 

Similar results are obtained by ATLAS

#### The Higgs couplings and the Higgs boson mass

The measured coupling modifiers of the Higgs boson to fermions and heavy gauge bosons, as functions of fermion or gauge boson mass, v is the vacuum expectation value of the BEH field  $m_{\rm F}$ 

CMS: H $\rightarrow$ 4-lepton final states m<sub>H</sub> = 125.04 ± 0.12 GeV

#### the triumph of the Standard Model

- A lot of experiments have conducted to the established of the Standard Model, from the experiment proving the existence in nature of the electron (Thomson, 1897), the discovery of the atomic nucleus structure (Rutherford, 1911), the discovery of the J/ $\psi$  (BNL, SLAC, 1974), to the discovery of W and Z bosons, validating electroweak unification (CERN 1983), the discovery of the top quark (FNAL 1995), till the Higgs boson discovery at CERN in 2012.
- The Large Hadron Collider (LHC) is conducting an in-depth examination of the Standard Model of particle physics through a plethora of high-precision measurements.
- These efforts not only validate the theory in known regimes but also seek potential deviations that could hint at new physics beyond the Standard Model.

## Standard Model precision studies at the LHC

Standard Model crosssection measurements.

- The measurements are corrected for branching fractions, compared to the corresponding theoretical expectations.
- Similar results from CMS

## Top quark physics at LHC

Summary of LHC and Tevatron measurements of the toppair production cross-section as a function of the centreof-mass energy compared to the NNLO QCD calculation complemented with NNLL resummation (top++2.0).

Summary of the ATLAS and CMS measurements from top quark decay. The results are compared with the LHC and Tevatron+LHC  $m_{top}$  combinations.

- The Standard Model, while incredibly successful see available results from LHC investigations, is clearly not the ultimate theory of nature.
- There are many open points and topics uncovered by this theory
  - **GRAVITY**: The Standard Model does not include gravity, which is described by **General Relativity**. There is no quantum theory of gravity in the Standard Model.
  - **DARK MATTER**: Observations of galaxies and cosmic phenomena indicates the presence of **dark matter**, which interacts gravitationally but not electromagnetically, weakly, or strongly.
  - **DARK ENERGY**: The accelerated expansion of the universe is attributed to **dark energy**, a mysterious force that the Standard Model does not address.
  - **MATTER-ANTI MATTER Asymmetry**: The universe is dominated by matter; The Standard Model includes CP violation (charge-parity asymmetry), but it is insufficient to explain the observed asymmetry

- **NEUTRINO MASSES**: Neutrinos are massless in the Standard Model, but experiments have shown they have tiny masses and undergo **oscillations** between flavours.
  - New physics, for example seesaw mechanism or sterile neutrinos?
- IS the 125 GeV SCALAR the STANDARD MODEL HIGGS BOSON?
  - **HYERARCHY Problem**: The Higgs boson's mass is much smaller than expected given quantum corrections, which should drive it to extremely high values.
  - Why the Higgs boson is "naturally" light without <u>fine-tuning</u>?
    - **u** Higgs not elementary particle? SUperSYmmetry theory? Or other BSM models?
- STRONG CP Problem: The strong force, described by quantum chromodynamics (QCD), does not appear to violate CP symmetry, even though there is no apparent reason it shouldn't.
- **UNFICATION OF FORCES**: is the Standard Model the Energy $\rightarrow 0$  approximation of a more general theory?
  - The Standard Model describes the electromagnetic, weak, and strong forces but does not unify them into a single framework

- **NEUTRINO MASSES**: Neutrinos are massless in the Standard Model, but experiments have shown they have tiny masses and undergo **oscillations** between flavours.
  - New physics, for example seesaw mechanism or sterile neutrinos?
- IS the 125 GeV SCALAR the STANDARD MODEL HIGGS BOSON?
  - **HYERARCHY Problem**: The Higgs boson's mass is much smaller than expected given quantum corrections, which should drive it to extremely high values.
  - Why the Higgs boson is "naturally" light without <u>fine-tuning</u>?
    - Biggs not elementary particle? Or other BSM models?
- **STRONG CP Problem**: The strong force, described by quantum chromodynamics (QCD), does not appear to violate CP symmetry, even though there is no apparent reason it shouldn't.
- **UNFICATION OF FORCES**: is the Standard Model the Energy $\rightarrow 0$  approximation of a more general theory?
  - The Standard Model describes the electromagnetic, weak, and strong forces but does not unify them into a single framework

- The Standard Model, while incredibly successful see available results from LHC investigations, is clearly not the ultimate theory of nature.

  - MATTER-ANTI MATTER Asymmetry: The universe is dominated by matter; The Standard Model includes CP violation (charge-parity asymmetry), but it is insufficient to explain the observed asymmetry

#### High-Luminosity LHC

Long Term Schedule for CERN Accelerator complex

→ > 1 year until start of Long Shutdown 3 [postponed to 29 June 2026]
 → > 80% of the project budget of 1.1 BCHF already committed
 → The project is ready for LS3 installation start in 2<sup>nd</sup> half of 2026!

## HL-LHC projections

- HL-LHC complete full simulation studies very challenging and very expensive (resources) at this point in time
- Procedure adopted:
  - Start from published LHC Run 2 studies and/or
  - **Simplified simulation** (using for example, DELPHES)
  - Adapt to HL-LHC conditions
    - center-of-mass energy: center-of-mass energy:  $\sqrt{s} = 14 \text{ TeV}$
    - pileup:  $30 \rightarrow 140$  or 200
    - Final statistics: 3000 fb<sup>-1</sup> per experiment
    - simulated detector and reconstruction performance
- Systematic uncertainties, Baseline Scenario: the increase of the systematic experimental uncertainties is compensated by the superior HL-LHC detector performance:
  - detector and trigger performance comparable to Run 2:
    - Studied improvements to object reconstruction and the impact of detector upgrades, using full simulation with pile-up
  - most experimental uncertainties scaled down with  $\sqrt{L}$
  - theoretical uncertainties scaled by 1/2 with respect to current values
  - 1% luminosity uncertainty

#### 58

#### The Higgs Potential

$$\mathcal{L} = T - V = \frac{1}{2} \partial_{\mu} \phi \partial^{\mu} \phi - \left(\frac{1}{2} \mu^2 \phi^2 + \frac{1}{4} \lambda \phi^4\right)$$

in SM, this potential is fully defined by two parameters, that can be inferred by the v.e.v.  $\nu$  and the Higgs boson mass  $m_h$ 

Expanding around the minimum, 
$$\phi = v + h$$
:  
 $V(h) = \lambda v^2 h^2 + \lambda v h^3 + \frac{1}{4} \lambda h^4 = m_h^2 = 2\lambda v^2$   $\lambda_3 = \lambda v = m_h^2/2v$   
 $\lambda_4 = \lambda/4 = mh^2/8v^2$ 

Higgs boson pair (HH) production allows to probe *directly* the Higgs boson self-interaction and, ultimately, the shape of the Higgs potential.

> ➔Any deviation from the self-interaction predicted by the SM would be a sign of new physics!

V-663  $\frac{1}{2}m_h^2h^2 + \lambda_3h^3 + \mu_4$  $\lambda_4 h^4$ Higgs triple Higgs quartic mass term coupling coupling н Н

#### HH production – recent updates

#### **Snowmass update 2021-2022**

ATLAS  $\gamma\gamma$ bb+bbtt combination: **3.2** $\sigma$ CMS updated  $\gamma\gamma$ bb results, added  $\gamma\gamma$ WW,  $\gamma\gamma\tau\tau$ , ttHH(bbbb)

→ ~5 $\sigma$  SM HH significance with a backof-the-envelope calculation

Negative logarithm of the combined likelihood ratio comparing different  $\kappa_{\lambda}$  hypotheses to an Asimov dataset constructed under the hypothesis of  $\kappa_{\lambda} = 1$  assuming four different uncertainty scenarios.

## New HL-LHC prospects results ATLAS for the *European Strategy for Particle Physics Update 2025-206*

- ATLAS and CMS are about to submit new Prospects results for HL-LHC, as input for the ongoing *European Strategy for Particle Physics Update* (ESPPU)
- These studies are based on new analyses developed for Run 2 LHC data
- They produce very exciting new prospects, wrt to what shown in occasion of last ESPPU and Snowmass

 $\kappa_{\lambda} = 1.0^{+0.48} \rightarrow < 50\%$  uncertainty with just one experiment  $\rightarrow$  expect an accuracy of ~30% when combining ATLAS and CMS prospects! Public document on ATLAS + CMS Combination coming soon, stay tuned!

## Higgs couplings and $\Gamma_{\rm H}$ at e<sup>+</sup>e<sup>-</sup> colliders

61

- $\sigma(e^+e^- \rightarrow ZH, H \rightarrow ZZ^*)$  is proportional to  $g^2_{HZZ} \cdot BR(H \rightarrow ZZ^*)$  which is proportional to  $g^4_{HZZ}/\Gamma_H \rightarrow extract \Gamma_H$
- The extraction of  $g_{HZZ}$  and  $\Gamma_{H}$  is *model independent*
- in hadron colliders some model assumption is needed, as shown already
- The knowledge of  $g_{\rm HZZ}^2$  allows the extraction of all other Higgs boson couplings
- $\sigma(e^+e^- \rightarrow ZH, H \rightarrow bb) \propto g^2_{HZZ} g^2_{Hbb} / \Gamma_H \rightarrow extract g_{Hbb}$
- $\sigma(e^+e^- \rightarrow ZH, H \rightarrow \tau\tau) \propto g^2_{HZZ} g^2_{H\tau\tau} / \Gamma_H \rightarrow \text{extract } g_{H\tau\tau}$
- ...

•

- but also  $e^+e^- \rightarrow \nu\nu H$ :  $\sigma(e^+e^- \rightarrow \nu\nu H) \propto g_{HWW}^2$
- $\sigma(e^+e^- \rightarrow \nu\nu H, H \rightarrow bb) \propto g^2_{HWW} g^2_{Hbb} / \Gamma_H \rightarrow \text{extract } g_{HWW} g_{Hbb}$

## Higgs self-coupling @ FCC-ee

- The accurate measurement of the ZH cross section can also give access to the Higgs boson self-coupling  $g_{HHH}$  via loops.
  - Higgs self-coupling contributes t ~ 2% to  $\sigma(e^+e^- \rightarrow ZH)$  @  $\sqrt{s}=240 \text{ GeV}$
- The dependence of the ZH cross section as a function of  $\sqrt{s}$  provides and independent, complementary method to access  $g_{HZZ}$  and  $g_{HHH}$
- the  $e^+e^- \rightarrow WW$  fusion  $\rightarrow H$  cross section gives independent contribution to this measurement
- Higgs self-coupling g<sub>HHH</sub> can be extracted with an accuracy of 33% (2 IPs) or 24% (4 IPs)

 $\delta c_Z$ : correction to the Higgs couplings to the gauge bosons  $\delta \kappa_{\lambda}$ : correction to the trilinear Higgs self-coupling:  $\delta \kappa_{\lambda}$ 

## Flavour Physics

- Peculiar structure of quark and lepton masses and their mixing angles in the Standard Model (SM)
  - these patterns could originate from new physics beyond the SM.
  - approximate flavour symmetries lead to the suppression of flavor-changing processes, which can be used to probe highenergy physics through precision measurements at FCC-ee.
- b and  $\tau$  decays, and b  $\rightarrow \tau$  transitions allow to test with third generation a general feature of many explicit BSM possibilities.

Particle species	$\mathbf{B}^{0}$	$B^+$	$B_s^0$	$\Lambda_b$	$\rm B_c^+$	$c\overline{c}$	$\tau^-\tau^+$
Yield $(\times 10^9)$	370	370	90	80	2	720	200

Yields of heavy-flavoured particles produced at FCCee for  $6 \times 10^{12}$  Z decays

Rare b-hadron decays with ττ pairs in the final
Lepton flavour violating τ decays state.

- Charged-current b-hadrons decays with a  $\tau v$  pair in the final state
- Lepton-universality tests in  $\tau$  decays

## **Rates at FCC-hh for 10** L = $ab^{-1}\sqrt{s} = 100$ TeV

Amazing potential, extreme detector and event reconstruction challenges

## The Higgs boson natural width

NN

- this width is too small to be measured directly from the line shape because of the limited mass resolution of order
   1 GeV achievable with the present LHC detectors
- → Probe the impact of  $\Gamma_{\rm H}$  in the "off-shell" region, i.e. studying the line shape of final states such as, for example, the four lepton final states.

Assuming on-shell and off shell couplings are equal:  $\mu_{\text{off-shell}}$   $\Gamma$ 

- Distribution of  $m_{4\ell}$  in the  $4\ell$  off-shell signal regions.
- Stacked histograms display the different predicted contributions after a fit to the data with SM couplings.
  - gold dot-dashed line shows the distribution after a fit to the no offshell ( $\Gamma_{\rm H}$ = 0 MeV) hypothesis
  - black points show the observed data, which is consistent with the prediction with SM couplings within one standard deviation
  - last bins contain the overflow.
- Bottom pad: ratio of the data or dashed histograms to the stacked histogram.

The no off-shell scenario with  $\Gamma_{\rm H}=0$  is excluded at 99.97%

$$\Gamma = 3.2^{+2.4}$$
 -1.7 MeV

# $\begin{array}{ll} \text{The kappa-framework} \\ (\sigma \cdot \text{BR}) \left( \text{gg} \rightarrow \text{H} \rightarrow \gamma \gamma \right) &= & \sigma_{\text{SM}}(\text{gg} \rightarrow \text{H}) \cdot \text{BR}_{\text{SM}}(\text{H} \rightarrow \gamma \gamma) \\ & & \text{narrow width approximation} \end{array} \cdot \frac{\kappa_{\text{g}}^2 \cdot \kappa_{\gamma}^2}{\kappa_{\text{H}}^2} \end{array}$

This is example for the Higgs boson produced by gluon-gluon (gg) fusion processes, decaying to  $\gamma\gamma$  final states

introduce  $\kappa$  as the ratio between the measured Higgs boson coupling and the one predicted by SM  $\kappa = measured \ coupling/predicted \ coupling$ 

Production		Decay	Total width
$\kappa_j^2 = \sigma_j / \sigma_j^{\rm SM}$	or	$\kappa_j^2 = \Gamma^j / \Gamma_{\rm SM}^j$	$\Gamma_H = \frac{\kappa_H^2 \cdot \Gamma_H^{\rm SM}}{1 - B_{\rm BSM}}$

Reflects the possibility allow for the possibility of Higgs boson decays to invisible or untagged BSM particles.

- assumes SM like coupling structure  $(J^{CP} = 0^{++}) \rightarrow$  only account for rates
- kappas correspond to tree-level H couplings to the different particles
- <u>in Standard Model:</u>  $\kappa_i = 1$

## From the kappa framework to EFT studies

- The kappa framework is "easy" to understand, model independent, but it is not appropriate when looking for small deviations of Higgs coupling from SM predictions
- Ideally one would like to combine information from rates, differential distributions, and CP properties
- Also, this framework does not include correlations with other important physics quantities in the theory
- → move to an approach based to EFT

dimension-6 dimension-8  

$$\mathcal{L} = \mathcal{L}_{SM} + \sum \frac{c_i}{\Lambda^2} \mathcal{O}_i^{d=6} + \sum \frac{c_i}{\Lambda^4} \mathcal{O}_i^{d=8} + \dots$$
BSM effects SM particles

- *A* is the scale where new heavy degrees of freedom exists, and the EFT breaks down
- C<sub>i</sub> are Wilson coefficients

## From the kappa framework to EFT studies

- The kappa framework is "easy" to understand, model independent, but it is not appropriate when looking for small deviations of Higgs coupling from SM predictions
- Ideally one would like to combine information from rates, differential distributions, and CP properties
- Also, this framework does not include correlations with other important physics quantities in the theory
- → move to an approach based to EFT

Look for deviations in kinematic distributions

#### From the $\kappa$ -framework to EFT studies

- The  $\kappa$ -framework is "easy" to understand but it is not appropriate when looking for small deviations of Higgs coupling from SM predictions
- Ideally one would like to combine information from rates, differential distributions, and CP properties
- Also, this framework does not include correlations with other important physics quantities in the theory
- → move to an approach based to EFT
  - Well-defined theoretical approach
  - Assumes New Physics states are heavy
  - Write Effective Lagrangian with only light (SM) particles
  - BSM effects can be incorporated as a momentum expansion

## Effective Field Theory studies

- Effective Field Theories EFTs
- Key principles:
  - EFT describes physics at a given energy scale by incorporating relevant degrees of freedom while parametrizing unknown high-energy effects.
  - It provides a universal method to study low-energy phenomena without requiring detailed knowledge of the fundamental high-energy theory.
  - EFT organizes interactions in a power series of suppression factors, typically in terms of the ratio  $E/\Lambda$ , where  $\Lambda$  is the cutoff scale of new physics.

- $\Lambda$  is the scale where new heavy degrees of freedom exists, and the EFT breaks down
- C<sub>i</sub> are Wilson coefficients
# Standard Model EFT – Higgs couplings

it is critical to progress on the experimental and theoretical accuracy on electroweak quantities: addressing this point is one of the most important points of the FCC scientific programme

•  $\delta g_{H}^{xx}$  is the accuracy on the coupling of the Higgs boson to xx initial/final states

Higgs couplings estimated with similar or better accuracy than what yielded by the  $\kappa$ -framework

# Standard Model EFT: new physics

95% probability bounds on the interaction scale  $\Lambda/\sqrt{C_i}$  associated to each displayed Operator.

It's a naïve estimate of when new physics might become relevant, based on Wilson coefficients.

Barbara Mele

75

Table 129 The baseline FCC-ee 16-years programme with four interaction points, showing the centre-of-mass energies, instantaneous luminosities for each IP, integrated luminosity per year summed over 4 IPs corresponding to 185 days of physics per year and 75% efficiency, in the order Z, WW, ZH, tt̄. The luminosity is assumed to be half the design value for machine commissioning and optimisation during the first two years at the Z pole, the first two years at the WW threshold, and the first year at the tt̄ threshold. (Should the order of the sequence be modified to either Z, ZH, WW, tt̄ or ZH, WW, Z, tt̄, the ZH stage would start with two years at half the design luminosity followed by two years at design luminosity, while the WW stage would run afterwards for only one year but at design luminosity.) The luminosity at the Z pole (the WW threshold) is distributed as follows:  $40 \text{ ab}^{-1}$  at 88 GeV,  $125 \text{ ab}^{-1}$  at 91.2 GeV, and  $40 \text{ ab}^{-1}$  at 94 GeV ( $5 \text{ ab}^{-1}$  at 157.5 GeV, and  $5 \text{ ab}^{-1}$  at 162.5 GeV). The number of WW events include all  $\sqrt{s}$  values from 157.5 GeV up.

Working point	Z, years 1-2	Z, later	WW, years $1-2$	WW, later	ZH	$t\overline{t}$	
$\sqrt{s}$ (GeV)	88, 91, 94		157, 163		240	340 - 350	365

# Linear Collider Facility

Figure 2: (a) Unpolarised cross-sections of important e<sup>+</sup>e<sup>-</sup> processes as a function of the centre-of-mass energy [35]. (b) Precisions on various Higgs couplings based on the 250 GeV and 550 GeV runs of Table 1. Sensitivity to probing BSM effects in H → ss has been shown in [37].

# Linear colliders

- Several challenges posed by a high-luminosity, high-energy linear collider. One in particular:
- The *ILC*: ... the tiny beams need to be collided with an accuracy of a fraction of their size, **so less than a nanometre!**
- ATF2 test facility in Japan: a purpose-built final-focus test beamline in Japan, an international collaboration has developed the controls and instrumentation needed to achieve these challenging parameters.
  - Goal 1 Achievement of small (37 nm) beam size: demonstration of finalfocus system based on local chromaticity correction;
  - Goal 2 Control of beam position: demonstration of beam orbit stabilization with nano-meter precision at the IP, using intra-pulse feedback.
- ATF2 achieved the result of 65 nm beam size at low bunch charge and with a relaxed  $\beta^*$ 
  - ATF2 should have reached a small spot size several years long before the 2011 earthquake that stopped this beam test

In Higgs compositeness models, the Higgs boson is not an elementary scalar like in the Standard Model (SM) but rather a composite state arising from a new strongly interacting sector. Sensitivity as a function of the typical coupling g\* and of the typical mass m\* of the composite sector that delivers the Higgs boson.

reach on new physics of a 10 TeV muon collider with 10 ab<sup>-1</sup> integrated luminosity.

"Others" indicates all other proposed future colliders. This includes expectations from FCC-hh

# **European Strategy for Particle Physics Steps in the Update Process**

### **1. Mandate by the CERN Council:**

The update process begins when the CERN Council issues a **mandate to review and update the current strategy**. This mandate outlines the scope, goals, and timeline for the update.

### **2.** Community Involvement and Call for Input:

A **public call for input is issued**, inviting contributions from the global particle physics community, including researchers, institutions, and national funding agencies. This step ensures that a wide range of perspectives and ideas are considered.

#### **3. Establishment of the Physics Preparatory Group (PPG):**

A **Physics Preparatory Group (PPG)** is formed, consisting of experts from the field. This group is responsible for collecting input, organizing discussions, and preparing a draft of the updated strategy. The PPG typically includes representatives from CERN, member states, and prominent physicists.

#### 4. Open Symposium:

An Open Symposium is held, gathering scientists and stakeholders to discuss the input received and the key scientific questions that the updated strategy should address. This symposium serves as a platform for debate 23-27 June 2025 on the future direction of the field, including potential projects, experiments, and technologies.

### **5. Drafting the Strategy Update:**

Based on the discussions and input, the **PPG drafts the updated strategy**. This draft, **the Briefing Book**, outlines the recommended scientific priorities, technological developments, and necessary investments for the coming years.

### 6. Submit the European Strategy Update recommendations to the CERN Council:

The Briefing Book is reviewed by the European Strategy Group (ESG), which includes representatives from CERN, member states, and observer states. Additional feedback is sought to refine and adjust the recommendations. A final document based is issued by the ESG to the CERN Council

**ESPP Update** 2024-2026

23-27 June 2025

Monte Verità in Ascona, 1-5 December 2025

## **INFN: activities & R&D**

The FCC project poses many technological challenges including:

- The damping ring and the injectors
- **Radiofrequency cavities**
- **Beam dipoles and quadrupoles**
- Machine/detector interface

INFN has promoted/financed **specific R&D** projects that can significantly contribute to the current European Strategy and the one in preparation.

Among these projects there is also the **Muon Collider.** 

- □ INFN community involved in the study of SRF cavities, high field magnets for the cooling cell , and in the study of the interaction region, the injector and dumping ring, and the detector
- It is essential to carry out an R&D experiment that demonstrates the feasibility of a high-energy muon collider → Demonstrator

FCC-ee IR description

**Italian interest and contributions** 

### Muon ionization cooling principle

#### **Strong Italian contributions**

Details on Roberto Losito presentation

Simulation of transverse emittance well reproduced by <u>MICE data</u>

## Muon Collider facility ov

Rapid acceleration is crucial:

- Linac takes muons at 255 MeV and bring them to 1.25 GeV.
- Two stages of Recirculating Linac, RLA1 from 1.25 GeV to 5 GeV and RLA 2 from 5 GeV to 63 GeV.

A  $\mu^+$  and  $\mu^-$  bunch must be brought to 5 TeV. Most promising schema: chain of rapid cycling synchrotrons (RCS) with repetition rate of 5 Hz. Alternative: Fixed-Field Alternating Gradient.

Survival rate of 90% per RCS required  $\rightarrow$  ultrafast acceleration, E<sub>gain</sub> ~10ish GeV per turn.

### Study and R&D:

- Magnets
  - hybrid magnets have strong fixed-field, they are superconducting magnets interleaved with normal conducting magnets.
  - shapes of fast ramping magnet and design possible power converter.
- RF: determine the exact frequency

# First design of $\sqrt{S} = 10$ TeV collider ring almost complete

#### Main challenges to have high performance:

- Very small beta-function ~1.5 mm.
- Maintain short bunches.

Magnet: assumed 16 T HTS dipoles or 11 T Nb<sub>3</sub>Sn. Final focus based on HTS.

### Study and R&D

- Study magnet limitations
  - stress, protection, etc. against bore diameter vs. magnetic field for different conductor material and temperature.

HTS magnets R&D synergic with others proposed facilities with relevant applications in no HEP activities, for example fusion.

## **Exploratory Site Studies**

- Initiates at LINAC 4
- Integrates existing SPL design
- Transfer to Prevessin via SPS
- Series of Cut & Cover construction on Prevessin Site
- Injection to SPS beneath existing buildings.
- Transfer via TI12 & TI18 into the LHC
- Injection from the LHC into the Collider Ring at equidistant points from the Experimental Cavern

# **NFN** Detector concept for $\sqrt{s} = 3$ TeV

The following full-simulation detector studies with BIB focus on  $\sqrt{s} = 3$  TeV, but the findings and results also apply to the 10 TeV case because of the similarity in the BIB characteristics.

6

## **Preparation of the INFN Input to the ESPPU**

- Kick-off meeting of the INFN community on 6 and 7 May 2024, Rome, Centro Congressi Frentani:
  - strong support for the FCC-integrated project
  - support for R&D for future innovating particle colliders
- A **Working Group,** coordinated by a **Steering Committee,** was established to foster the contribution of the INFN community to the preparation of the Input to be submitted to the ESPPU (by 31/03/2025)
- Wrap-up meeting today ( 4 February 2025) Milano Bicocca University/INFN
  - Presentations of the work & documents produced by the WGs.
    - Several of these documents will be submitted to the Strategy along with the National Input

# Organisation

## Working group:

- Presidents of Scientific Committees
- Directors of National Labs
- Chair of the INFN Machine Advisory Committee (MAC) + Chair of the INFN-Acceleratori
- Chair of the Computing Committee (C3SN)
  - representatives of the INFN Communications Office
- Steering Group: C. Borca (ECR), M. Ciuchini, S. Malvezzi, A. Nisati, R. Tenchini
- Various meetings in INFN units and labs
- Some initiatives/workshops organized by theorists
- Two dedicated ECR events (see Cecilia's talk)
