Outline

- Deep-inelastic heavy-ion reactions
 - short history
 - product yield distribution assessed with different techniques
- Accessing yrast structures in neutron-rich nuclei around ^{48}Ca – successful combination of the thick-target and thin-target methods
- New yrast structures in nuclei located around ^{208}Pb
- Realistic $V_{\text{low-}k}$ shell model calculations in the vicinity of ^{208}Pb and their predictive power
- Perspectives for discrete yrast gamma-ray spectroscopy „east” and „south-east” of ^{48}Ca or ^{208}Pb with high intensity stable beams

Angular distribution of gamma rays from the ^{206}Bi product

**Results on the most neutron-rich
nuclei around ^{208}Pb produced
in the $^{208}\text{Pb} + ^{238}\text{U}$ reaction
and studied by using the $\gamma-\gamma-\gamma$
coincidence thick-target technique
with GAMMASPHERE**

**Realistic shell model calculations
of YRAST STATES using the $V_{\text{low-}k}$ approach –
residual n-n interaction derived
from the free nucleon–nucleon potential**

To get the $V_{\text{low-}k}$ effective interaction we used:

Computational Environment for Nuclear Structure (CENS)

*CD-Bonn potential, $\Lambda=2.2 \text{ fm}^{-1}$,
model spaces: ($Z=50-82, N=82-126$) , ($Z=50-82, N=126-184$)*

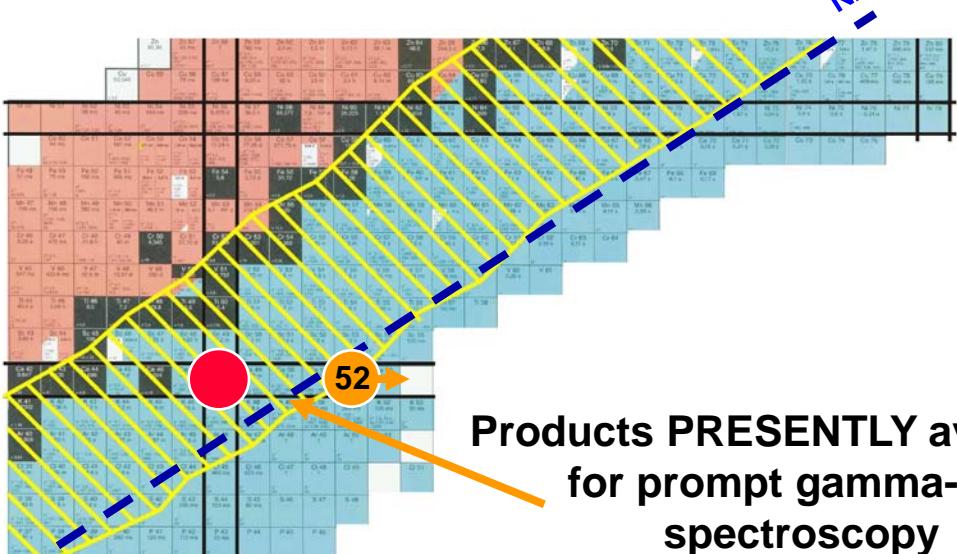

^{208}Pb

For shell-model calculations we used:
computer code OXBASH,

s.p.s. energies from experiment;

$^{48}\text{Ca} + ^{238}\text{U}$

$E_{\text{lab}} = 330 \text{ MeV}$

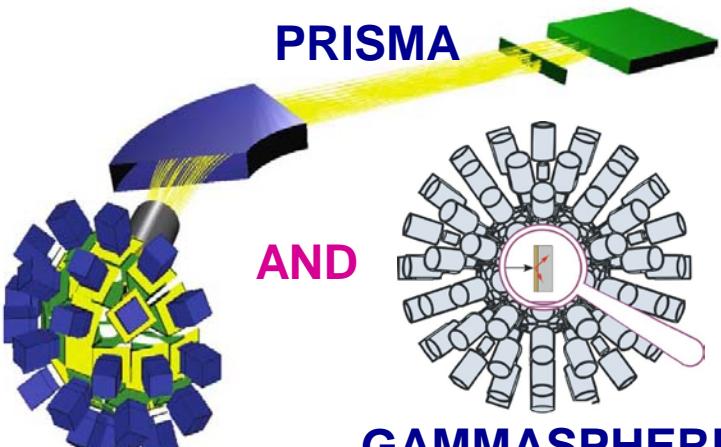

Products PRESENTLY available
for prompt gamma-ray
spectroscopy

Conclusions and Outlook

- Discrete in-beam gamma-ray spectroscopy with deep-inelastic reactions turned out to be efficient in elucidating yrast structures in many neutron-rich nuclei.
- Combination of **thick-target** (standalone γ -ray array: GASP, EUROBALL, GAMMAPSHERE) and **thin-target** (γ -ray array coupled to a magnetic spectrometer: CLARA+PRISMA, EXOGAM+VAMOS) **techniques** were particularly successful in identifying yrast structures in weakly populated neutron-rich species .
- **Discrete in-beam gamma-ray spectroscopy** of deep-inelastic reactions products will benefit from high intensity beams, although only beams with moderately higher intensity will be of use.
Experiments using these higher intensity beams and modern tracking germanium arrays should extend the in-beam spectroscopy toward more neutron-rich nuclei by at least 3 mass units.
