# Origin of the heavy elements

A large neutron flux is difficult to be maintained!!!!

## s(low) process

Mild neutron density  
 $n_n \sim 10^7$  (and  $\sim 10^{11}$ )

Asymptotic giant branch (AGB) and massive stars

## i(termediate) process

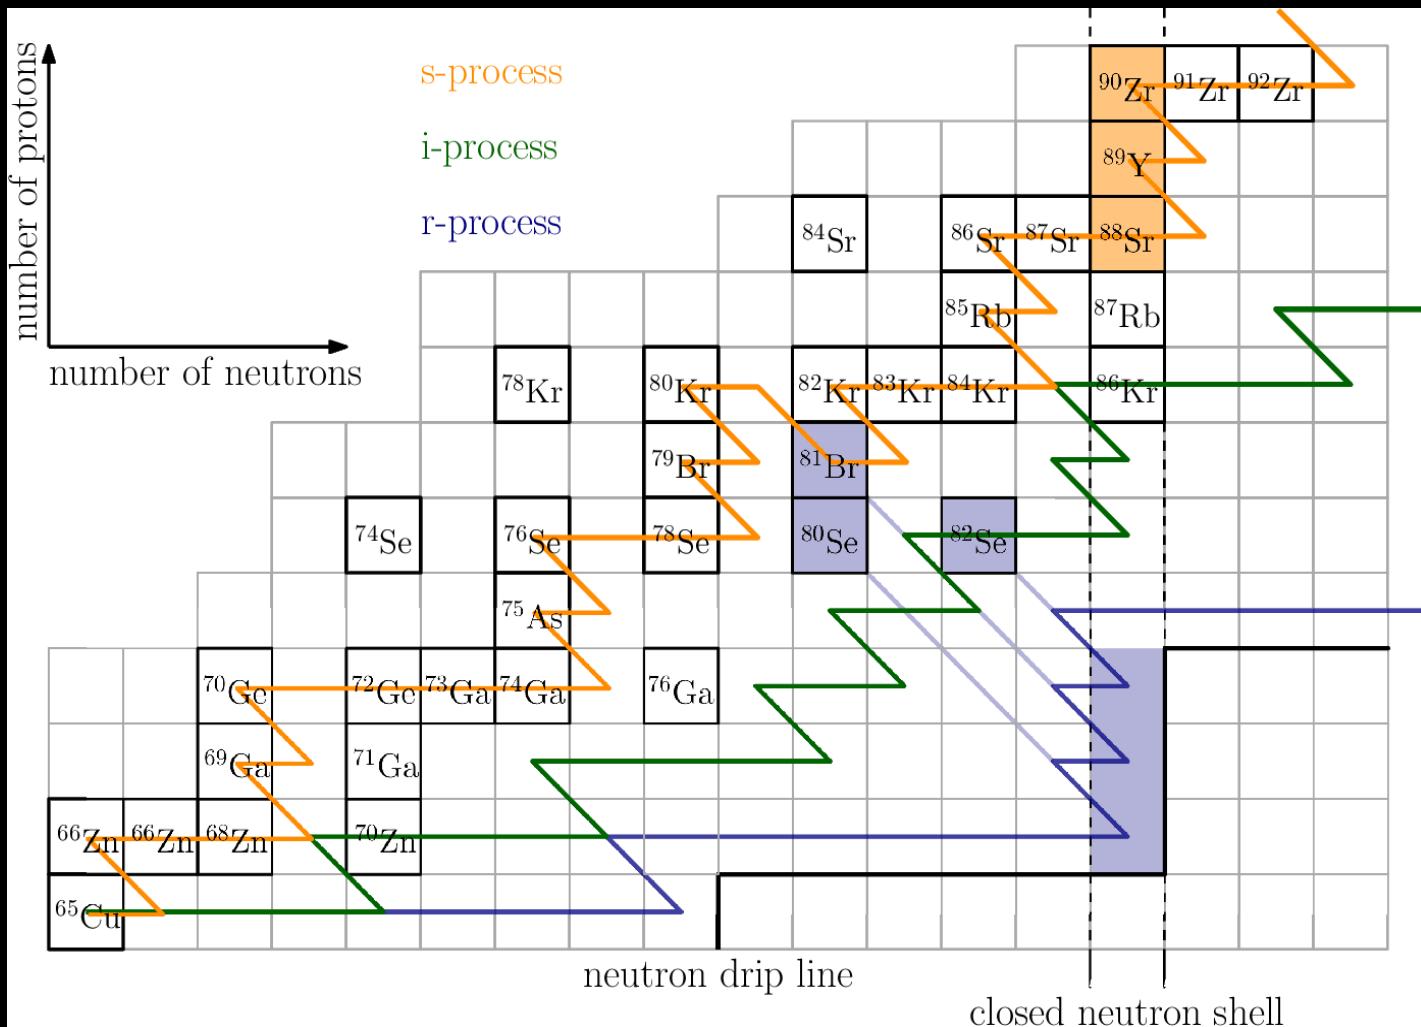

Intermediate neutron density  $n_n \sim 10^{15}$

AGB, rapidly accreting white dwarfs, massive stars, etc.

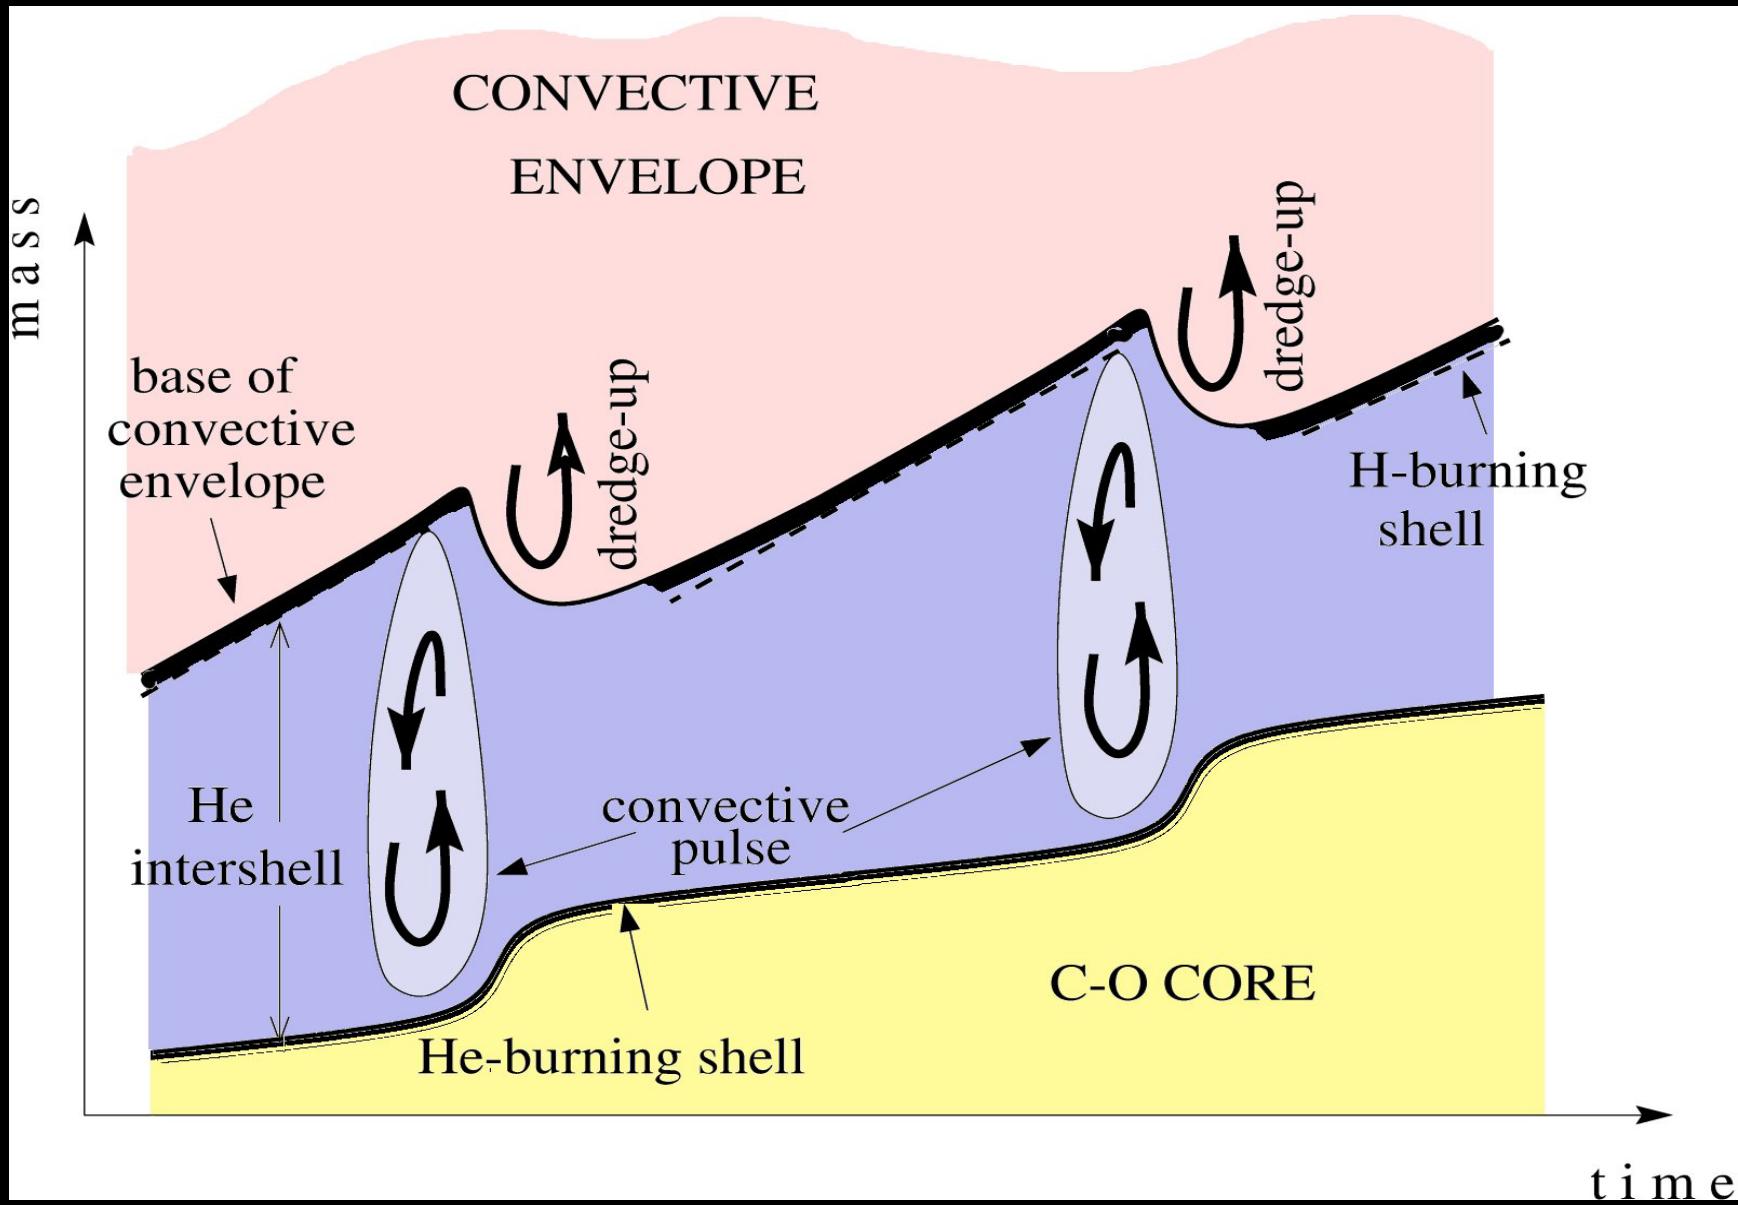

## r(apid) process

High neutron density  
 $n_n \gtrsim 10^{21}$

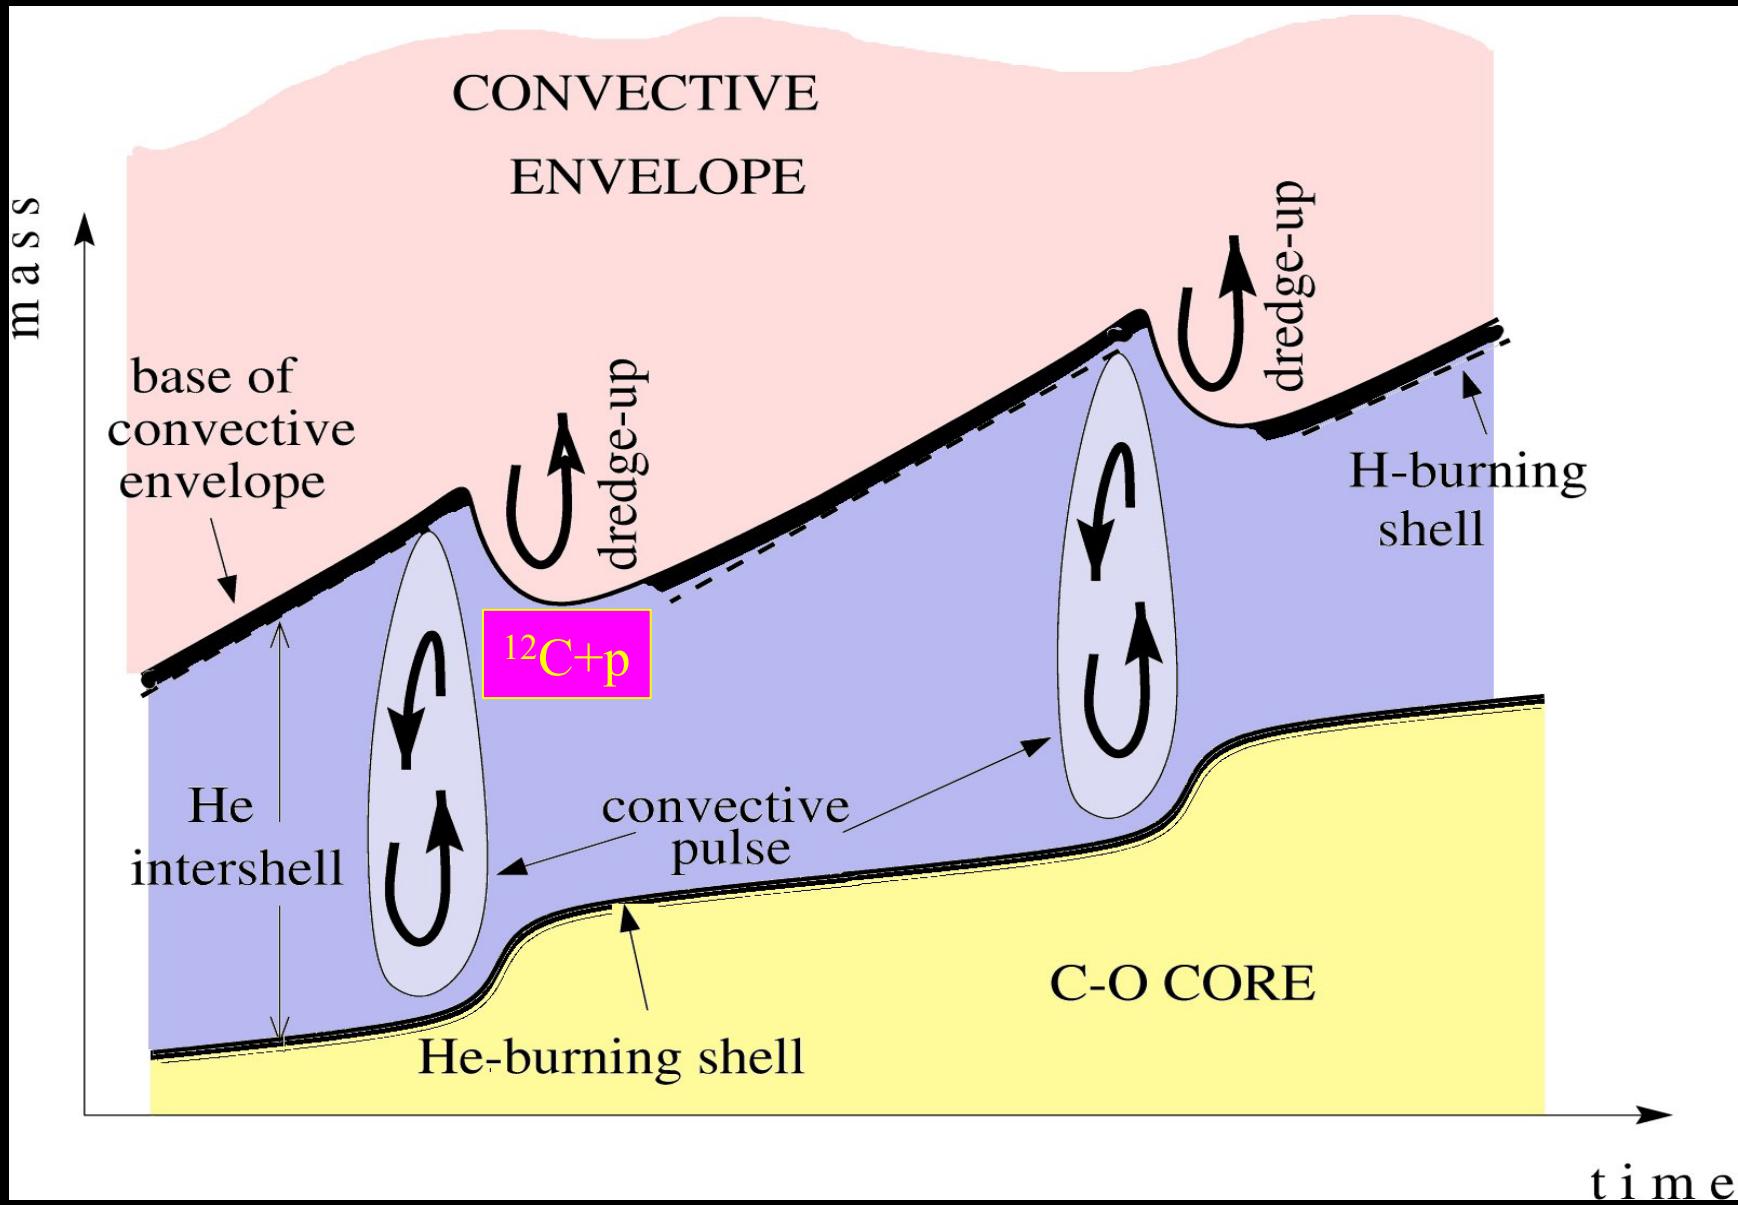

Collapsars, magnetars and compact binary mergers

# F.R.U.I.T.Y. FULL-Network Repository of Updated Isotopic Tables & Yields

The screenshot shows the F.R.U.I.T.Y. web interface against a background of a nebula. The interface is divided into three main sections: Model Selection, Output Selection, and Output Format.

**Model Selection:**

- Mass ( $M_{\odot}$ ): A dropdown menu with options including "Standard".
- Metallicity ( $Z$ )<sup>(1)</sup>: A dropdown menu with options including "Standard".
- Initial Rotational Velocity (IRV)<sup>(2)</sup>: A dropdown menu with options including "0".
- $^{13}\text{C}$  Pocket<sup>(9)</sup>: A dropdown menu with options including "Standard".

**Output Selection:**

- Nuclides Properties:**
  - Elements<sup>(3,4)</sup>
  - Isotopes<sup>(5)</sup>
  - s-process<sup>(6)</sup> : [Hs/I], [Pb/I], ...
- Yields<sup>(7)</sup>:**
  - Net<sup>(8)</sup>
  - Total
- Z:** All
- A:** All
- Yield Options:** All, Z: All

**Output Format:**

- Multiple Table format<sup>(10)</sup>**
- Single Table format<sup>(11)</sup>**
- All Dredge Up Episodes<sup>(12)</sup>**
- Final Composition**
- Final**

Buttons at the bottom include "Back to Physics", "Search", and "Reset". A link "NOTES ON THE MODELS (pdf file)" is also present.

Vescovi+ 2020

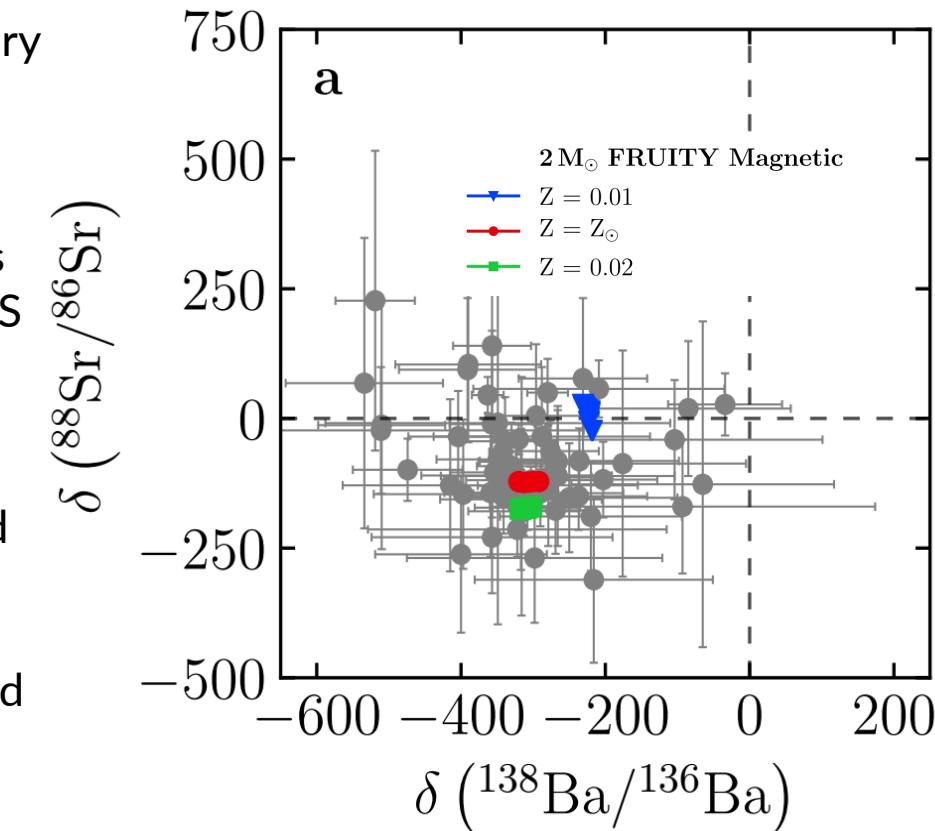

# The effectiveness of presolar grain measurements

- Correlated Sr and Ba isotope analyses of more MS grains using the new generation of instruments are needed to better quantify the MS grain distribution to determine the data variability, which will help to assess the primary mechanism responsible for the  $^{13}\text{C}$  formation

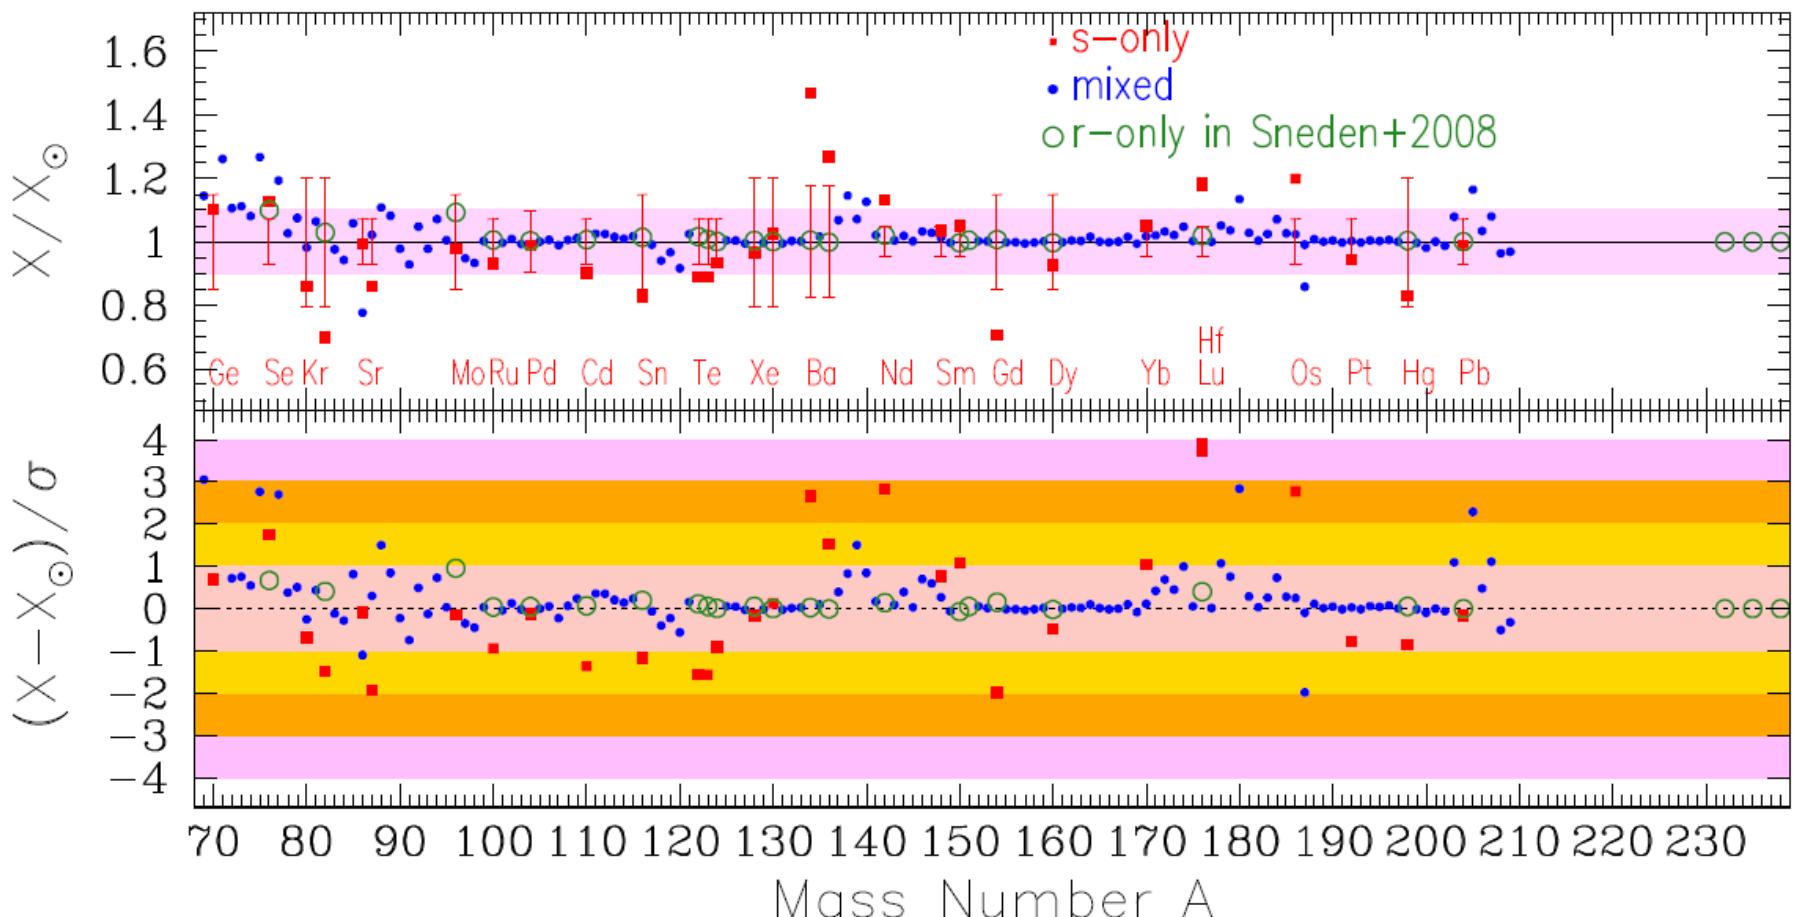

- Nuclear Experiments: AGB model predictions for  $\delta^{88}\text{Sr}$  and  $\delta^{138}\text{Ba}$  rely directly on the MACS values of  $^{86}\text{Sr}$ ,  $^{88}\text{Sr}$ ,  $^{136}\text{Ba}$ , and  $^{138}\text{Ba}$

- Current AGB model uncertainties in  $\delta^{88}\text{Sr}$  and  $\delta^{138}\text{Ba}$  are controlled by uncertainties in the  $^{86}\text{Sr}$  ( $\pm 10\%$ ) and  $^{136}\text{Ba}$  ( $\pm 3\%$ ) MACS values, respectively, which correspond to  $\sim 200\%$  and  $\sim 50\%$  uncertainties, respectively

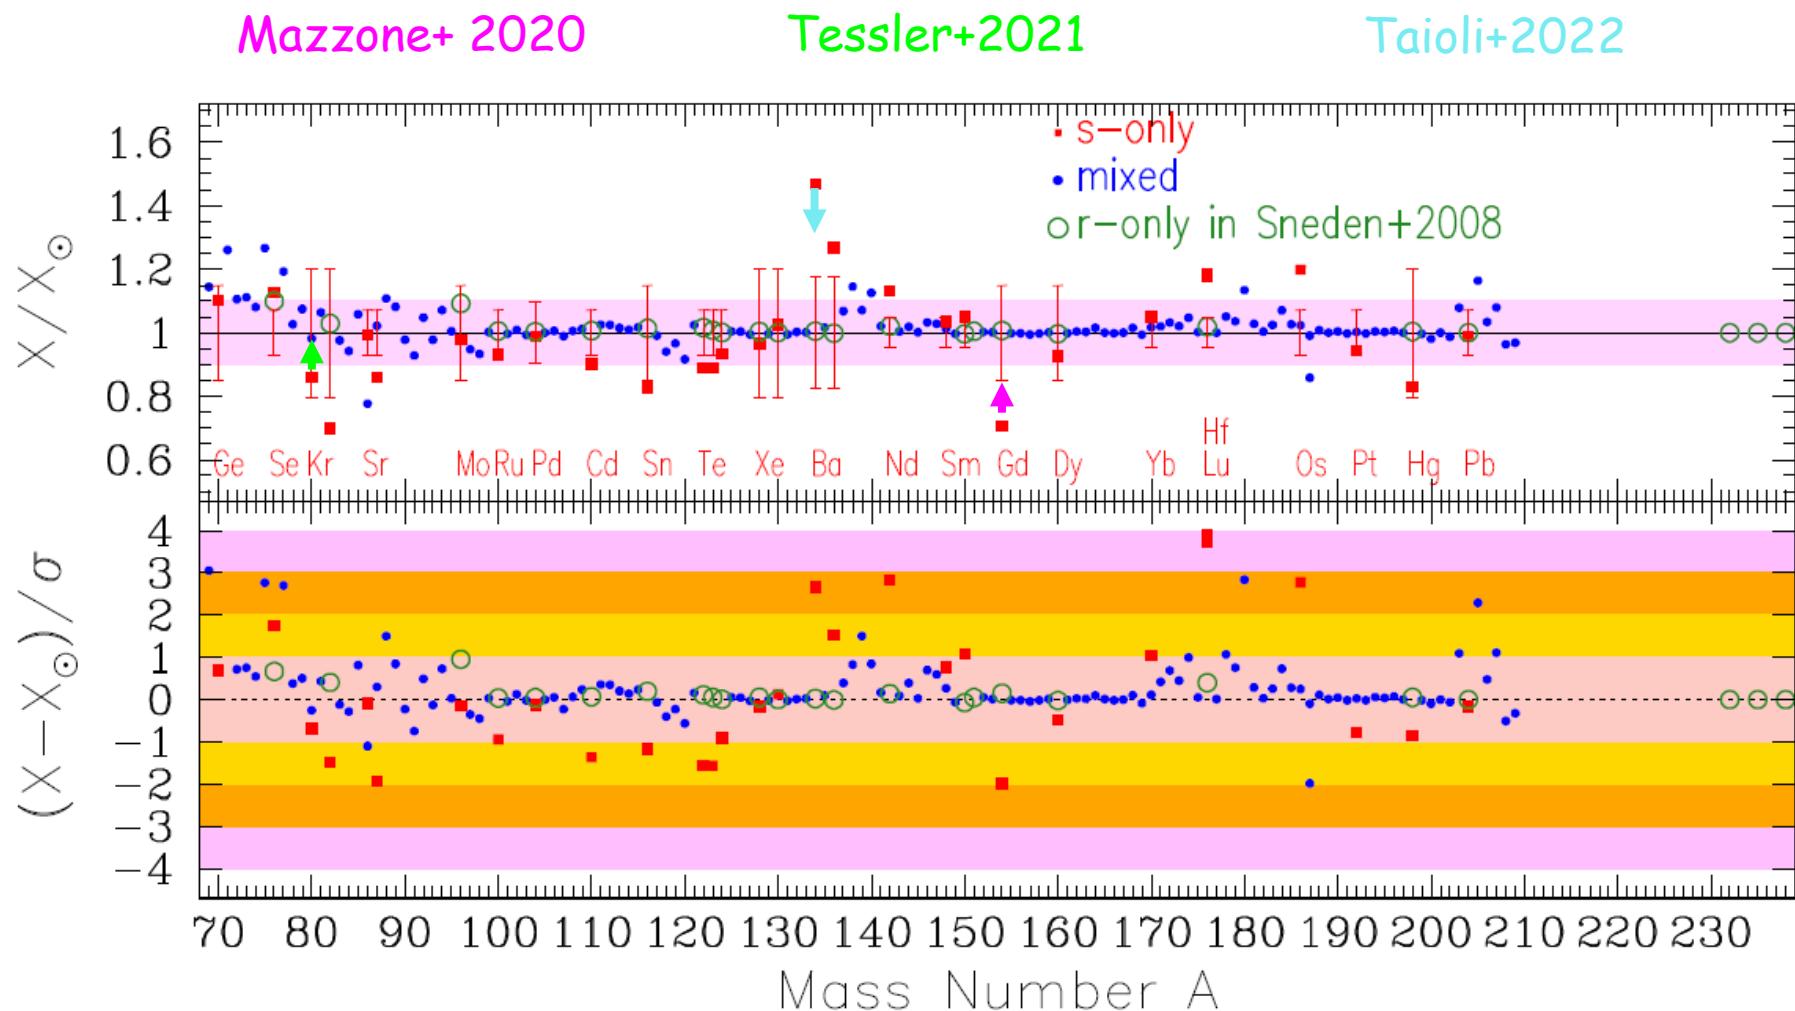

- As the full range of  $\delta^{88}\text{Sr}$  values observed among MS grains is only  $\sim 400\%$ , new measurements of  $^{86}\text{Sr}$  MACS values are needed to reduce model uncertainties

# Second effective constraint for the s-process: s-only Solar distribution

# Second effective constraint for the s-process: s-only Solar distribution

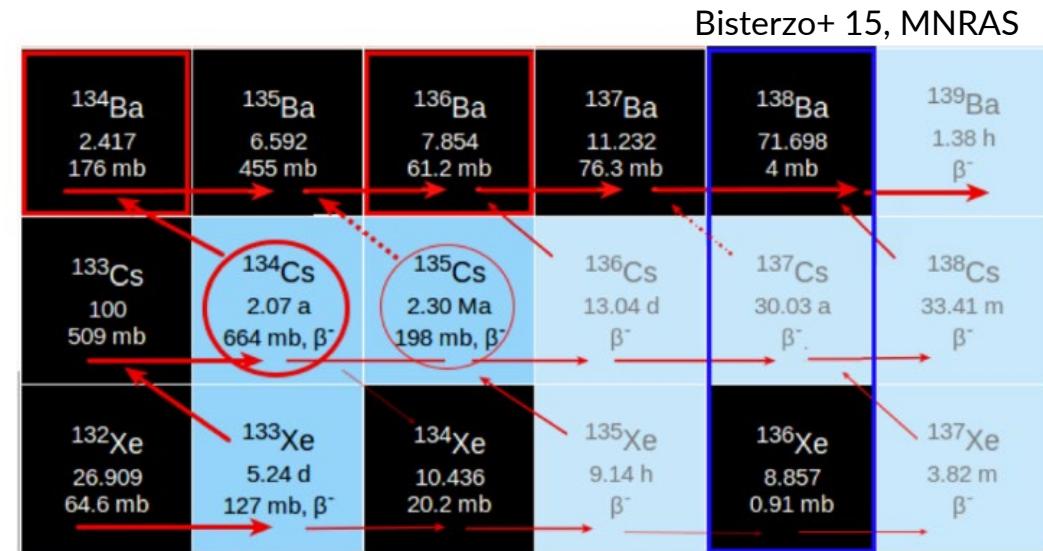

Prantzos+ 2020

# Branchings in the s-process: Cesium isotopes

- The chain of branching points at the Cs isotopes is of particular interest not only for understanding the  $^{135}\text{Cs}/^{133}\text{Cs}$  ratio in the Early Solar System

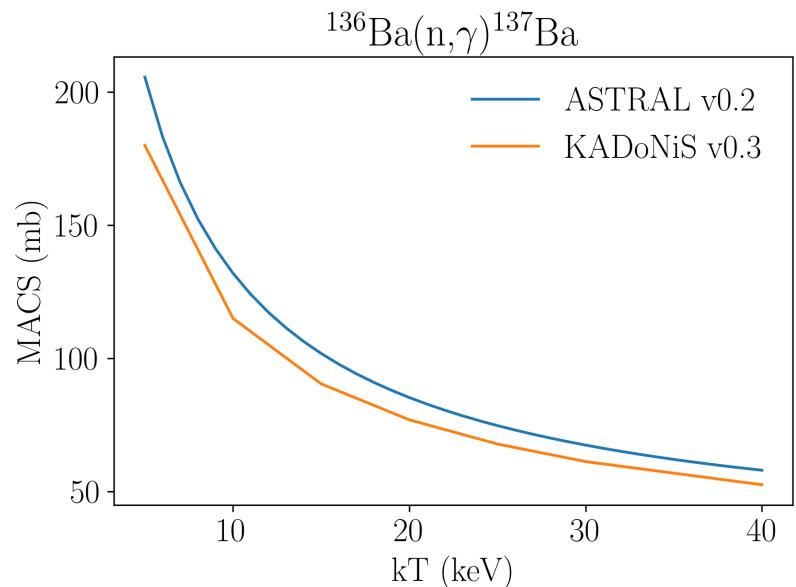

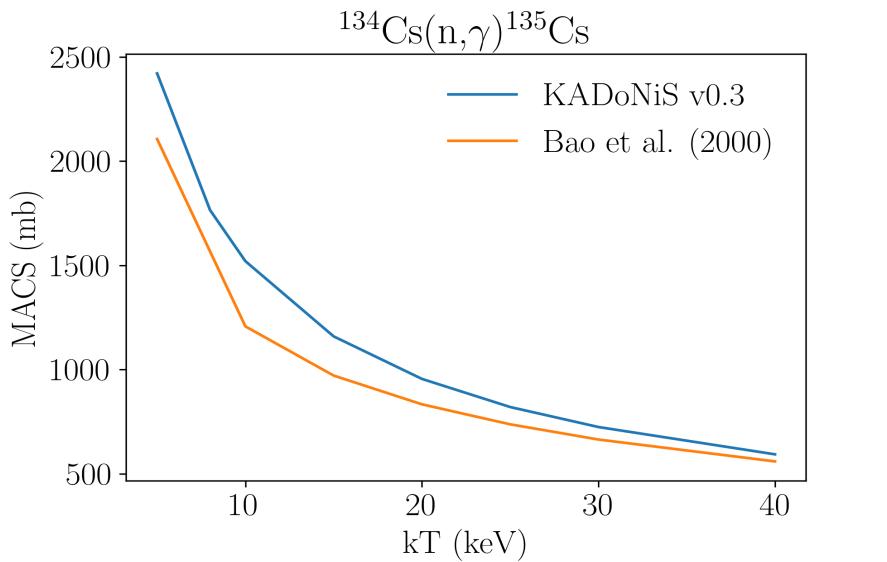

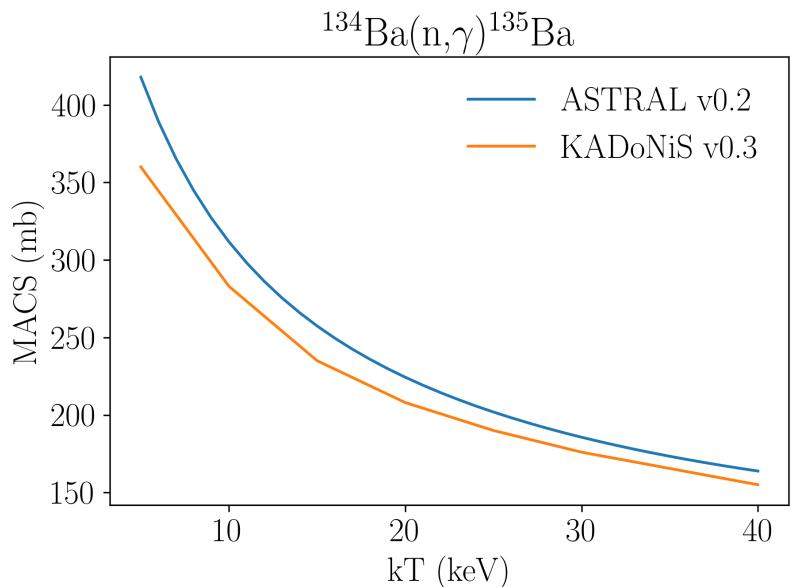

- It affects the isotopic composition of Ba and in particular the relative abundances of the two s-only nuclei  $^{134}\text{Ba}$  and  $^{136}\text{Ba} \rightarrow$  important for explaining their measured ratio in meteorites (e.g., Busso+ 21, Palmerini+21, Taioli+ 22)

- The half lives of both  $^{134}\text{Cs}$  and  $^{135}\text{Cs}$  decrease by orders of magnitude in stellar conditions  $\rightarrow$  act as branching point
- The branching point at  $^{134}\text{Cs}$  ( $T_{1/2} = 2$  Myr) allows the production of the long-living isotope  $^{135}\text{Cs}$

# Branchings in the s-process: Cesium isotopes

- The neutron-capture cross section of  $^{135}\text{Cs}$  has been experimentally determined, while the  $^{134}\text{Cs}(n,\gamma)$  cross section has **only** been semi-empirically estimated (Patronis+ 04)

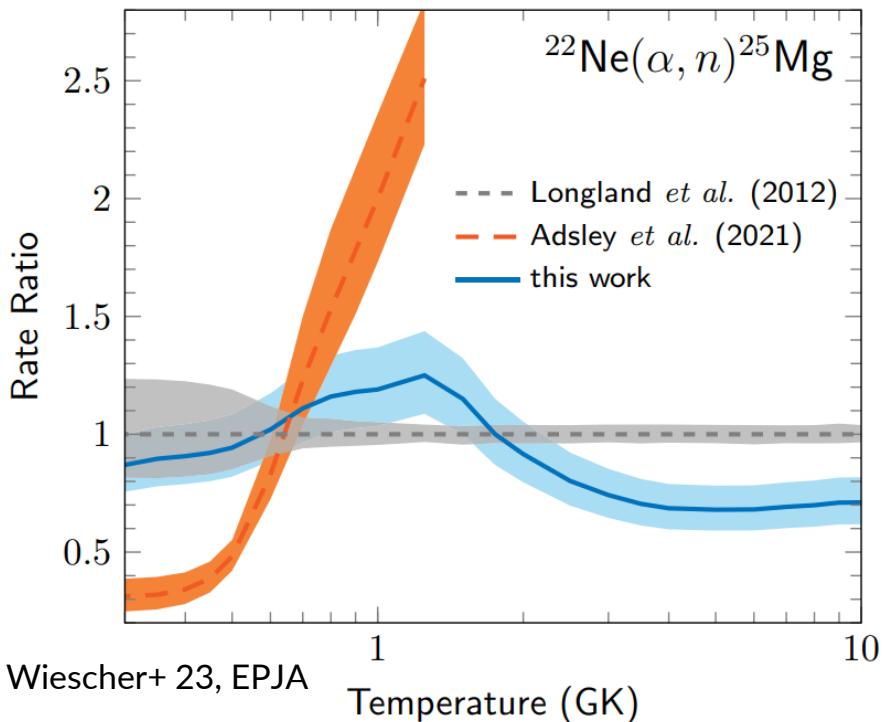

- Re-evaluated cross sections, → systematically higher due to the new (higher by ~5%) adopted gold cross section as a reference

# Branchings in the s-process: Cesium isotopes

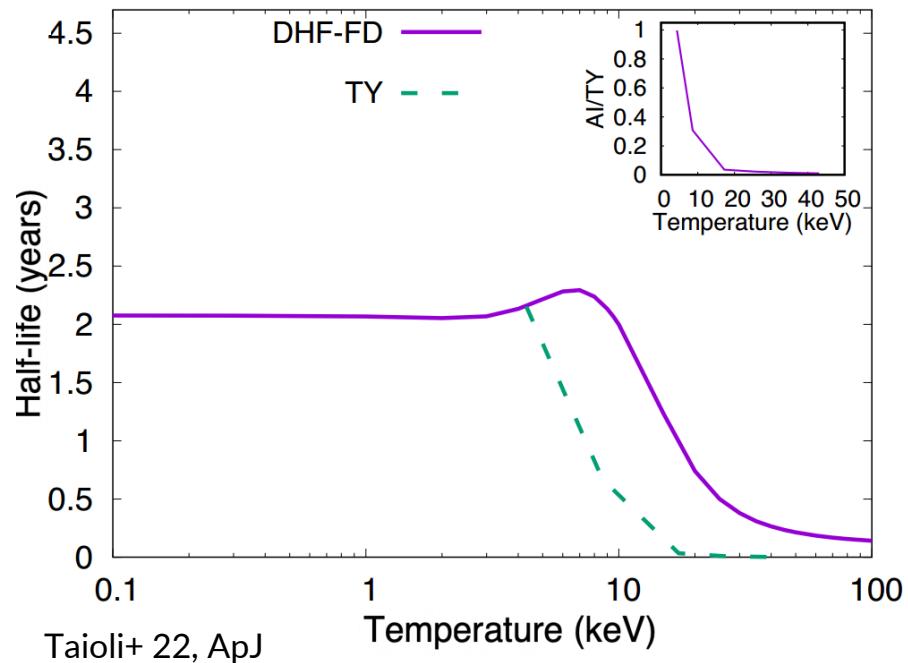

## Neutron sources

- $^{22}\text{Ne}(\alpha, n)^{25}\text{Mg}$  reaction rate uncertain by a **factor ~3**: direct and indirect measurements (e.g., Adsley+21, Shahina+ 24)

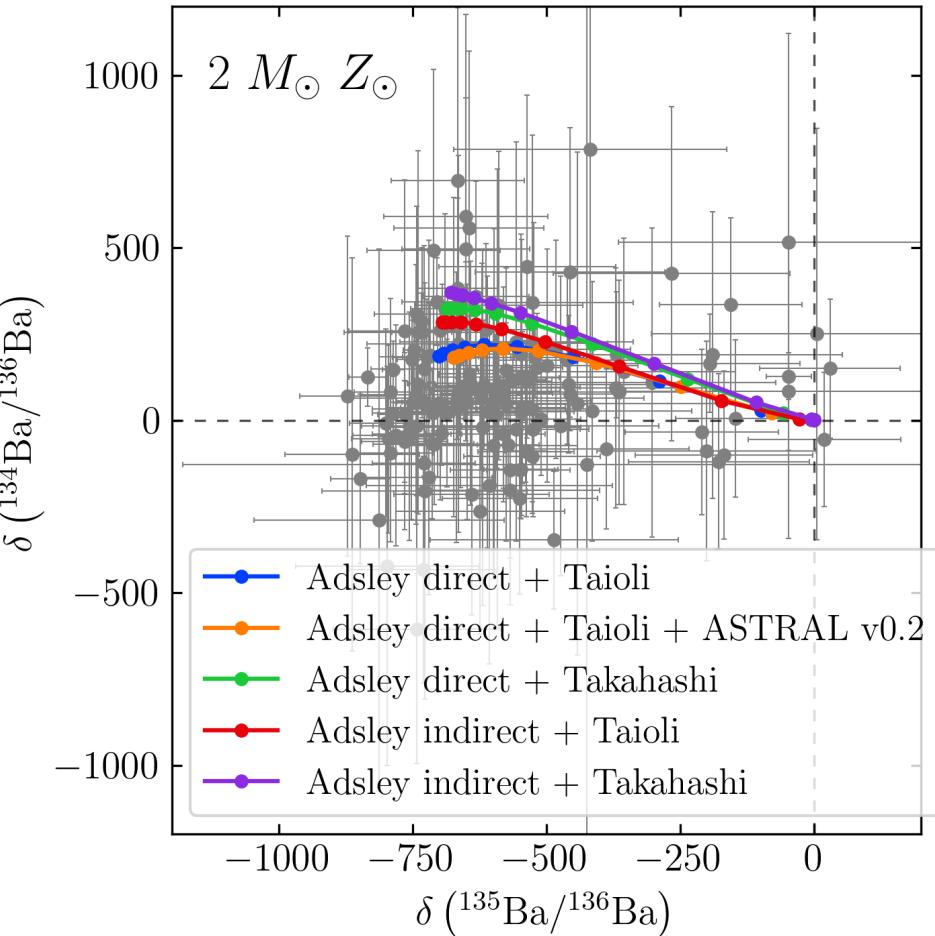

## $\beta^-$ decays

- Theoretical  $^{134}\text{Cs}$   $\beta^-$  rate is reduced up to a factor of 8 for  $T > 10^8$  K w.r.t Takahashi & Yokoi 87 (Li+ 21, Taioli+ 22)

# Branchings in the s-process: Cesium isotopes

- $^{22}\text{Ne}(\alpha, n)^{25}\text{Mg}$  reaction rate from Adsley+ 21 with indirect data and with direct data only
- $^{134}\text{Ba}(n, \gamma)$  and  $^{136}\text{Ba}(n, \gamma)$  from ASTRAL v0.2
- $^{134}\text{Cs} \beta^-$  rate from Takahashi & Yokoi 87 and Taioli+ 22
- $^{134}\text{Ba}/^{136}\text{Ba}$  ratio decreases with enhanced  $^{22}\text{Ne}(\alpha, n)^{25}\text{Mg}$  rate computed from directed data only
- $^{134}\text{Ba}/^{136}\text{Ba}$  ratio decreases with new  $^{134}\text{Cs} \beta^-$  rate
- $^{134}\text{Ba}/^{136}\text{Ba}$  ratio almost unchanged with revised n-capture rates
- **Better agreement: Adsley direct + Taioli model**

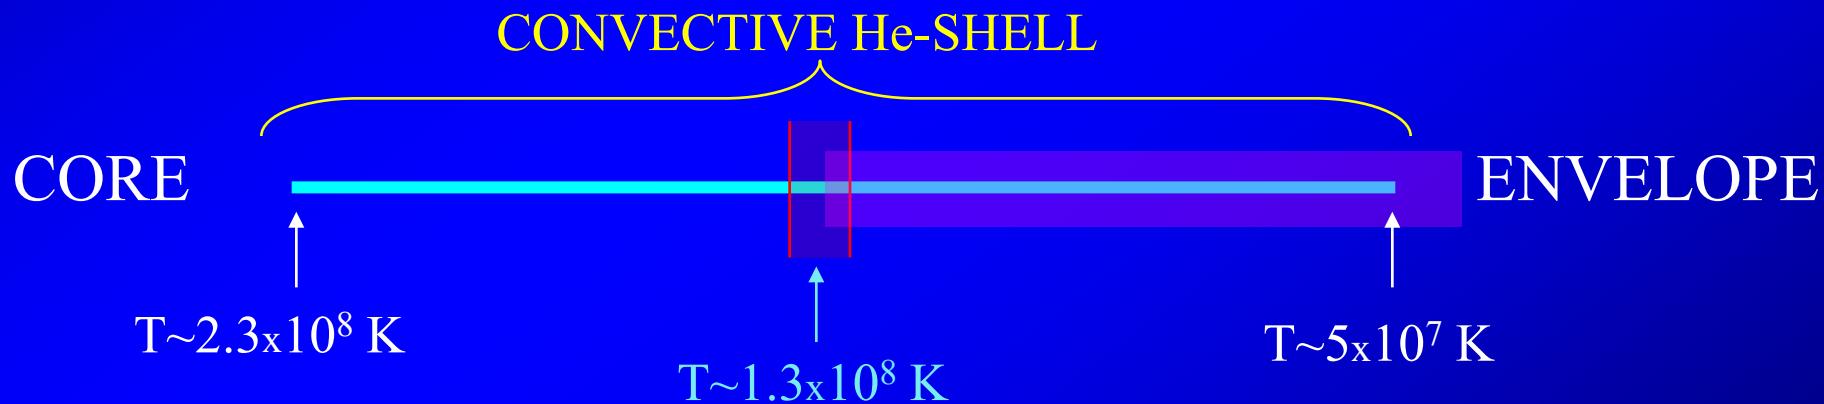

# The i-process

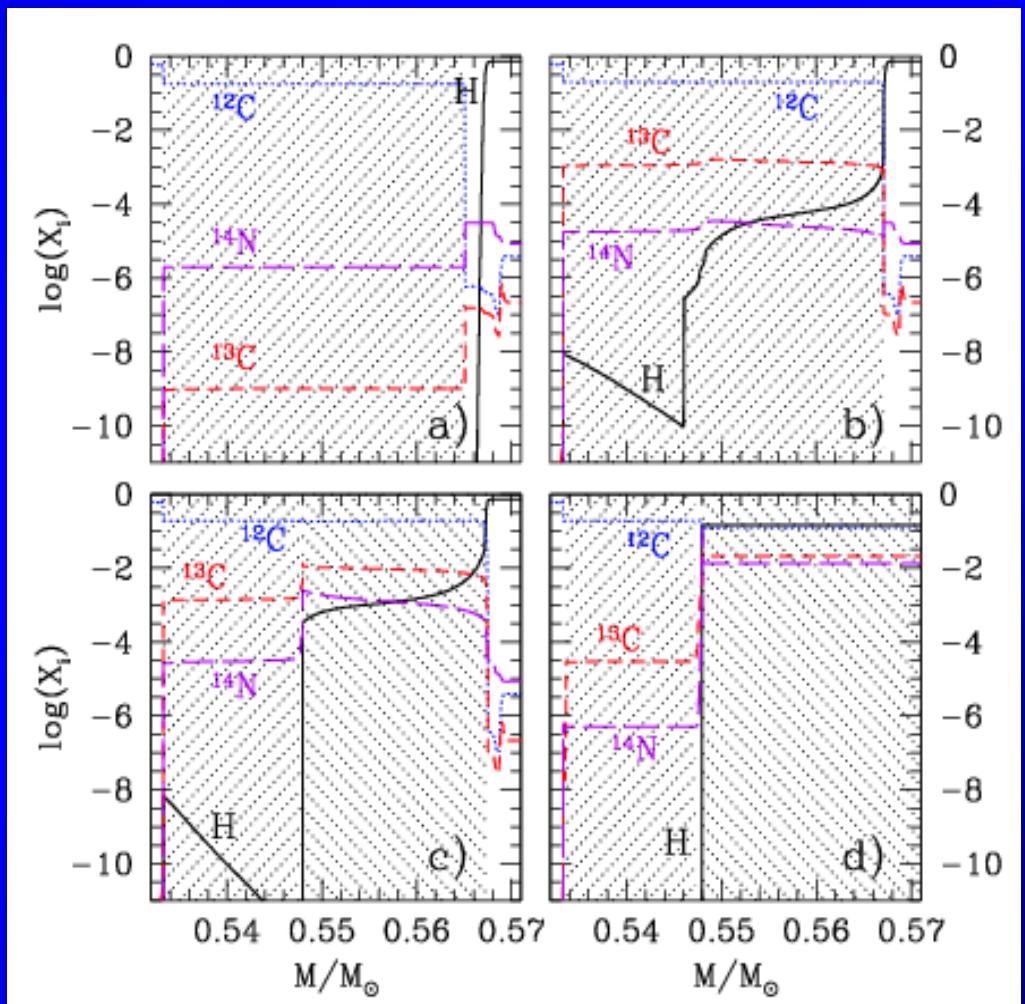

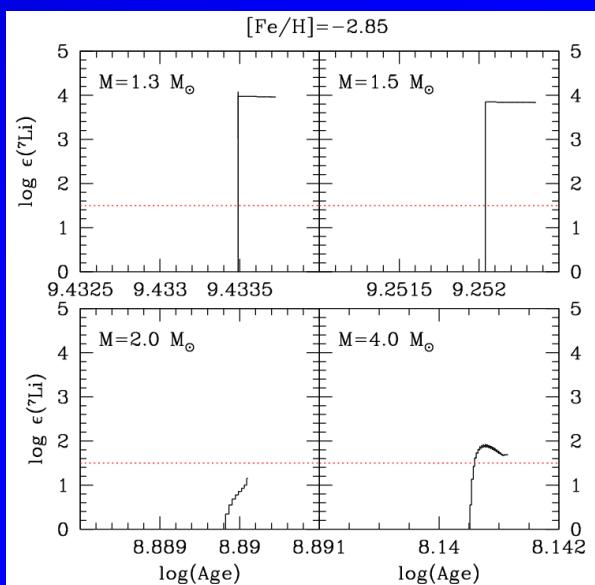

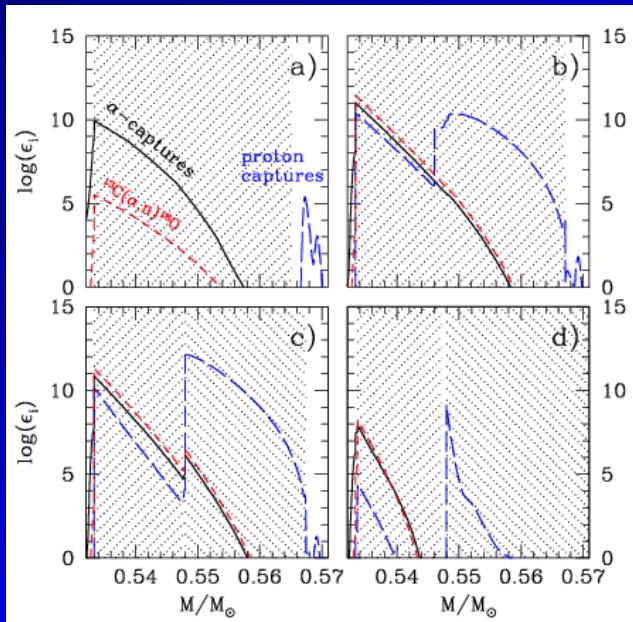

1. H-ingestion in low- $Z$  low-mass AGB stars
2. H-ingestion in rapidly accreting WDs
3. Massive AGBs stars at low  $Z$
4. He-accreting WDs

# Proton Ingestion Episode (PIE) and the intermediate neutron capture process (i-process)

- Low time steps → Time dependent mixing
- Rapid structure reaction → Coupling between physical and chemical evolution
- Large neutron densities ( $n_n > 10^{15} \text{ cm}^{-3}$ ) → 700 isotopes & 1000 reactions

# The effect of n-capture cross sections

# The effect of n-capture cross sections

# Take home message

- Presolar grains are powerful tools to calibrate stellar models;
- Accurate nuclear data are needed to further constrain stellar models;
- The i-process hosting site is still unknown and difficult to be modelled;
- A new series of challenging measurements are needed to constrain the i-process.

*That's all Folks!*
