Outline

- introduction
- bound-state eigenvalue problem
- light-front coupled-cluster method
 - Chabysheva and jrj, PLB 711, 417 (2012)
 - also next talk by Chabysheva
- sample application
- form-factor calculation
- summary

Introduction

- wish to compute hadron structure in terms of wave functions

- must truncate in some fashion
- the LFCC method avoids Fock-space truncation

Equations for wave functions

Solve $(\text{K.E.} + V_{\text{QCD}}) |p\rangle = E_p |p\rangle$ with $E_p = \sqrt{m_p^2 + p^2}$ and

Equivalent to coupled integral equations

•
•

Uncanceled divergences

- for example, the Ward identity of gauge theories is destroyed by truncation

- analog in Feynman perturbation theory
 - separate diagrams into time-ordered diagrams
 - discard time orderings that include intermediate states with more particles than some finite limit
 - destroys covariance, disrupts regularization, and induces spectator dependence for subdiagrams
- in the nonperturbative case, this happens not just to some finite order in the coupling but to all orders

Light-cone coordinates

Dirac, RMP 21, 392 (1949);

Brodsky, Pauli, and Pinsky, Phys. Rep. 301, 299 (1997).

- time: $x^+ = t + z$
- space: $\underline{x} = (x^-, \vec{x}_\perp)$, $x^- \equiv t - z$, $\vec{x}_\perp = (x, y)$
- energy: $p^- = E - p_z$
- momentum: $\underline{p} = (p^+, \vec{p}_\perp)$, $p^+ \equiv E + p_z$, $\vec{p}_\perp = (p_x, p_y)$
- mass-shell condition: $p^2 = m^2 \Rightarrow p^- = \frac{m^2 + p_\perp^2}{p^+}$

Mass eigenvalue problem

- Pauli and Brodsky, PRD **32**, 1993 (1985); 2001 (1985)

$$\mathcal{P}^- |\underline{P}\rangle = \frac{M^2 + P_\perp^2}{P^+} |\underline{P}\rangle, \quad \mathcal{P} |\underline{P}\rangle = \underline{P} |\underline{P}\rangle.$$

- no spurious vacuum contributions to eigenstates
 - $p^+ > 0$ for all particles
 - cannot produce particles from vacuum and still conserve p^+
 - (but difficult to analyze structure of physical vacuum)
- boost-invariant separation of internal and external momenta
 - longitudinal momentum fractions $x_i \equiv p_i^+ / P^+$
 - relative transverse momenta $\vec{k}_{i\perp} \equiv \vec{p}_{i\perp} - x_i \vec{P}_\perp$

Coupled-cluster (CC) method

- originated with Coester, Nucl. Phys. 7, 421 (1958) and Coester and Kümmel, Nucl. Phys. 17, 477 (1960), with applications to the many-body Schrödinger equation in nuclear physics.
- applied to many-electron problem in molecules by Čížek, J. Chem. Phys. 45, 4256 (1966).
- form eigenstate as $e^T |\phi\rangle$ where
 - $|\phi\rangle$ is product of single-particle states
 - terms in T annihilate states in $|\phi\rangle$ and create excited states, to build in correlations
 - truncate T at some number of excitations
- review: RJ Bartlett and M Musial, RMP 79, 291 (2007).

Light-front CC (LFCC) method

- wish to solve $\mathcal{P}^- |\psi\rangle = \frac{M^2 + P_\perp^2}{P^+} |\psi\rangle$.
- write eigenstate as $|\psi\rangle = \sqrt{Z} e^T |\phi\rangle$
 - Z controls normalization: $\langle \psi' | \psi \rangle = \delta(\underline{P}' - \underline{P})$.
 - $|\phi\rangle$ is the valence state, with $\langle \phi' | \phi \rangle = \delta(\underline{P}' - \underline{P})$.
 - T contains terms that only increase particle number.
 - T conserves J_z , light-front momentum \underline{P} , charge, ...
 - $p^+ > 0 \Rightarrow T$ must include annihilation and powers of T include contractions.
- construct $\overline{\mathcal{P}}^- = e^{-T} \mathcal{P}^- e^T$ and let P_v project onto the valence Fock sector. Then, have coupled system:

$$P_v \overline{\mathcal{P}}^- |\phi\rangle = \frac{M^2 + P_\perp^2}{P^+} |\phi\rangle \quad \text{and} \quad (1 - P_v) \overline{\mathcal{P}}^- |\phi\rangle = 0.$$

A soluble model

- light-front analog of the Greenberg–Schweber model
 - static fermionic source that emits and absorbs bosons without changing its spin

Chabysheva and jrh, PLB 711, 417 (2012);
Brodsky, jrh, and McCartor, PRD 58, 025005 (1998);
Greenberg and Schweber, N Cim 8, 378 (1958).

- not fully covariant
 - hides some of the power of the LFCC method, but is sufficient to show how the method can be applied.
 - states are all limited to having a fixed total transverse momentum \vec{P}_\perp , which we take to be zero.

Fock-state expansions

$$|\psi\rangle = \begin{array}{c} \longrightarrow \\ \longleftarrow \end{array} \psi_0 + \begin{array}{c} - \longrightarrow \\ \longrightarrow \\ \longrightarrow \end{array} \psi_1 + \begin{array}{c} - \longrightarrow \\ - \longrightarrow \\ \longrightarrow \\ \longrightarrow \end{array} \psi_2 + \dots$$

Instead, in LFCC:

$$T = \begin{array}{c} \diagup \\ \longrightarrow \end{array} t_1 \longleftarrow + \begin{array}{c} \diagup \\ \longrightarrow \\ \longrightarrow \\ \longrightarrow \end{array} t_2 \longleftarrow + \begin{array}{c} \diagup \\ \longrightarrow \\ \longrightarrow \\ \longrightarrow \\ \longrightarrow \end{array} t_3 \longleftarrow + \dots$$

$$e^T |\phi\rangle = \left[\begin{array}{c} 1 + \begin{array}{c} \diagup \\ \longrightarrow \end{array} t_1 \longleftarrow + \begin{array}{c} \diagup \\ \longrightarrow \\ \longrightarrow \end{array} t_1 \longleftarrow + \begin{array}{c} \diagup \\ \longrightarrow \\ \longrightarrow \\ \longrightarrow \end{array} t_1 \longleftarrow + \begin{array}{c} \diagup \\ \longrightarrow \\ \longrightarrow \\ \longrightarrow \\ \longrightarrow \end{array} t_2 \longleftarrow \\ + \begin{array}{c} \diagup \\ \longrightarrow \end{array} t_1 \longleftarrow \begin{array}{c} \longrightarrow \\ \longrightarrow \\ \longrightarrow \end{array} t_1 \longleftarrow + \begin{array}{c} \diagup \\ \longrightarrow \\ \longrightarrow \end{array} t_1 \longleftarrow \begin{array}{c} \longrightarrow \\ \longrightarrow \\ \longrightarrow \\ \longrightarrow \end{array} t_1 \longleftarrow + \begin{array}{c} \diagup \\ \longrightarrow \\ \longrightarrow \\ \longrightarrow \end{array} t_1 \longleftarrow \begin{array}{c} \longrightarrow \\ \longrightarrow \\ \longrightarrow \\ \longrightarrow \\ \longrightarrow \end{array} t_2 \longleftarrow \\ + \begin{array}{c} \diagup \\ \longrightarrow \\ \longrightarrow \\ \longrightarrow \\ \longrightarrow \end{array} t_3 \longleftarrow + \dots \end{array} \right] \begin{array}{c} \longrightarrow \\ \longrightarrow \end{array} \phi$$

Truncation

$$|\psi\rangle = \leftarrow \psi_0 + \begin{array}{c} \text{---} \leftarrow \\ \leftarrow \text{---} \end{array} \psi_1 + \begin{array}{c} \text{---} \leftarrow \\ \text{---} \leftarrow \\ \leftarrow \text{---} \end{array} \psi_2 + \dots$$

$$T = \leftarrow t_1 + \begin{array}{c} \text{---} \leftarrow \\ \leftarrow \text{---} \\ \text{---} \leftarrow \end{array} t_2 + \begin{array}{c} \text{---} \leftarrow \\ \text{---} \leftarrow \\ \leftarrow \text{---} \\ \text{---} \leftarrow \end{array} t_3 + \dots$$

$$e^T |\phi\rangle = \left[1 + \leftarrow t_1 + \leftarrow t_1 \leftarrow t_1 + \leftarrow t_1 \leftarrow t_1 \leftarrow t_1 + \begin{array}{c} \text{---} \leftarrow \\ \leftarrow \text{---} \\ \text{---} \leftarrow \end{array} t_2 + \begin{array}{c} \text{---} \leftarrow \\ \leftarrow \text{---} \\ \text{---} \leftarrow \\ \text{---} \leftarrow \end{array} t_2 \leftarrow t_1 + \begin{array}{c} \text{---} \leftarrow \\ \leftarrow \text{---} \\ \text{---} \leftarrow \\ \text{---} \leftarrow \\ \text{---} \leftarrow \end{array} t_2 \leftarrow t_1 \leftarrow t_1 + \begin{array}{c} \text{---} \leftarrow \\ \leftarrow \text{---} \\ \text{---} \leftarrow \\ \text{---} \leftarrow \\ \text{---} \leftarrow \\ \text{---} \leftarrow \end{array} t_2 \leftarrow t_1 \leftarrow t_1 \leftarrow t_1 + \dots \right] \leftarrow \phi$$

Effective Hamiltonian

- constructed from Baker–Hausdorff expansion.

- list only terms that connect the lowest Fock sectors.
- the self-energy contribution is the same in all Fock sectors
- contains all three of the diagrams analogous to those for the Ward identity in QED

Eigenvalue problems

In LFCC:

Exact solution

- in this special case, the exponential operator e^T generates the exact solution, with

$$t_{ls}(\underline{q}, \underline{p}) = \frac{-g}{\sqrt{16\pi^3 q^+}} \left(\frac{p^+}{p^+ + q^+} \right)^\gamma \frac{q^+ / P^+}{\mu_l^2 + q_\perp^2}.$$

- the fact that the self-energy loop is the same in the valence sector and the one-fermion/one-boson sector plays a critical role. It contributes

$$-\frac{g}{P^+} \int \frac{dq}{\sqrt{16\pi^3 q^+}} \theta(P^+ - q^+) \left(\frac{P^+ - q^+}{P^+} \right)^\gamma \sum_l (-1)^l t_{l\pm}(\underline{q}, \underline{P} - \underline{q}),$$

regulated by the PV ($l = 1$) term.

- the expression for the loop obtained in the valence sector is exactly what is needed to obtain the necessary cancellations.

Dirac form factor

- compute the Dirac form factor for the dressed fermion from a matrix element of the current $J^+ = \bar{\psi}\gamma^+\psi$
- the current couples to a photon of momentum q
- the matrix element is generally

$$\langle \psi^\sigma(\underline{P} + \underline{q}) | 16\pi^3 J^+(0) | \psi^\pm(\underline{P}) \rangle = 2\delta_{\sigma\pm} F_1(q^2) \pm \frac{q^1 \pm iq^2}{M} \delta_{\sigma\mp} F_2(q^2)$$

with F_1 and F_2 the Dirac and Pauli form factors.

- in the present model, the fermion cannot flip its spin; therefore, F_2 is zero, and we investigate only F_1

Expectation values

- expectation value for op \hat{O} : $\langle \hat{O} \rangle = \frac{\langle \phi | e^{T^\dagger} \hat{O} e^T | \phi \rangle}{\langle \phi | e^{T^\dagger} e^T | \phi \rangle}$
- direct computation requires infinite sum.
- define $\bar{O} = e^{-T} \hat{O} e^T$ and $\langle \tilde{\psi} | = \langle \phi | \frac{e^{T^\dagger} e^T}{\langle \phi | e^{T^\dagger} e^T | \phi \rangle}$
- then $\langle \hat{O} \rangle = \langle \tilde{\psi} | \bar{O} | \phi \rangle$ and
 $\langle \tilde{\psi}' | \phi \rangle = \langle \phi' | \frac{e^{T^\dagger} e^T}{\langle \phi | e^{T^\dagger} e^T | \phi \rangle} | \phi \rangle = \delta(\underline{P}' - \underline{P})$
- \bar{O} computed from Baker–Hausdorff expansion:
 $\bar{O} = \hat{O} + [\hat{O}, T] + \frac{1}{2} [[\hat{O}, T], T] + \dots$
- $\langle \tilde{\psi} |$ is a left eigenvector of $\bar{\mathcal{P}}^-$:
 $\langle \tilde{\psi} | \bar{\mathcal{P}}^- = \langle \phi | \frac{e^{T^\dagger} \mathcal{P}^- e^T}{\langle \phi | e^{T^\dagger} e^T | \phi \rangle} = \langle \phi | \bar{\mathcal{P}}^{-\dagger} \frac{e^{T^\dagger} e^T}{\langle \phi | e^{T^\dagger} e^T | \phi \rangle} = \frac{M^2 + P_\perp^2}{P^+} \langle \tilde{\psi} |$

L FCC approximation

- the form factor is approximated by the matrix element

$$F_1(q^2) = 8\pi^3 \langle \tilde{\psi}^\pm(\underline{P} + \underline{q}) | \overline{J^+(0)} | \phi^\pm(\underline{P}) \rangle,$$

with $\overline{J^+(0)} = J^+(0) + [J^+(0), T] + \dots$

- for this model, there are no contributions from fermion-antifermion pairs, so that

$$J^+(0) = 2 \sum_s \int \frac{d\underline{p}'}{\sqrt{16\pi^3}} \int \frac{d\underline{p}}{\sqrt{16\pi^3}} b_s^\dagger(\underline{p}') b_s(\underline{p}),$$

- only the first two terms of the Baker–Hausdorff expansion contribute to the matrix element
- the first term contributes $1/8\pi^3$

Evaluation of the form factor

- the left-hand wave function takes the form

$$l_{ls}^\sigma(\underline{q}, \underline{P}) = \delta_{\sigma s} \frac{-g}{\sqrt{16\pi^3 q^+}} \left(\frac{P^+ - q^+}{P^+} \right)^\gamma \frac{q^+ / P^+}{\mu_l^2 + q_\perp^2} \tilde{l}(q^+ / P^+)$$

with \tilde{l} the solution of a 1D integral equation

- if \tilde{l} is computed in quadrature, the integrals remaining in F_1 can be computed from the same quadrature rule for any chosen value of q^2
- if \tilde{l} is instead constructed as an expansion in g^2 , F_1 can also be constructed as an expansion
- in any case, in the limit of $q^2 \rightarrow 0$, we have $F_1(0) = 1$, consistent with the unit charge in the current $J^+ = \bar{\psi} \gamma^+ \psi$

Summary

- advantages of LFCC approach:
 - no Fock-space truncation.
 - no sector dependence or spectator dependence.
 - systematically improvable.
- future work:
 - QED (see 1203.0250 and talk by Chabysheva):
 - dressed-electron-state
 - dressed-photon state.
 - extend dressed-electron state to include e^+e^- .
 - muonium, positronium.
 - symmetry breaking in scalar theories.
 - QCD
 - holographic & full
