Beyond Dephasing: Scalable laser-plasma accelerators

via Traveling-wave electron acceleration

Alexander Debus¹, Klaus Steiniger¹, Finn-Ole Carstens¹, Richard Pausch¹, Julian Lenz¹, Franz Pöschel², René Widera¹, Sunita Chandrasekaran^{2,3}, Michael Bussmann^{2,1}, Ulrich Schramm¹

Dreams of reaching towards TeV-scale electron energies using plasma-based accelerators

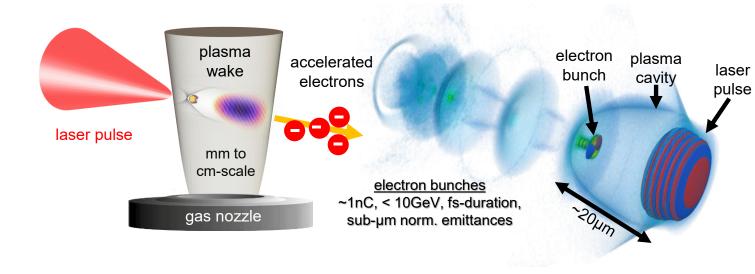

W. Leemans, E. Esarey, Phys. Today 62(3), 44 (2009)

Grand challenges in Laser-plasma accelerators for reaching electron energies beyond 10 GeV

- Dephasing limit
- Laser pulse guiding
- Self-phase modulation and laser pump depletion

Laser Plasma Accelerators (LPAs) are more compact and less costly

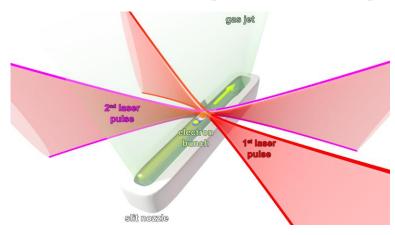

Beyond high-energy applications: Structured - light approaches enable control over LPA acceleration phase, Providing new ways to control electron injection and acceleration.

- Staging and beam transport is hard!
- Synchronization, Beam size matching, charge loss, Laser in- & out-coupling, emittance growth in beam transport, etc.

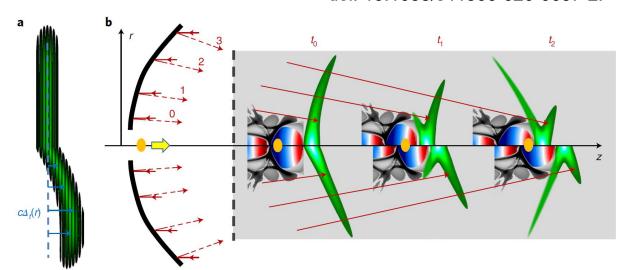

Dephasing-free laser-plasma accelerators use lasers that exploit spatio-temporally couplings

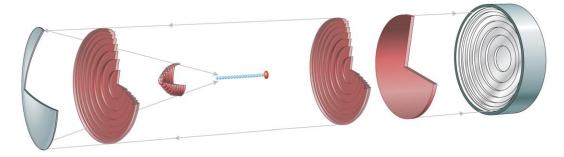

Phase-locked laser-wakefield electron acceleration

Traveling-Wave Electron Acceleration (TWEAC)

TWEAC circumvents major limitations:

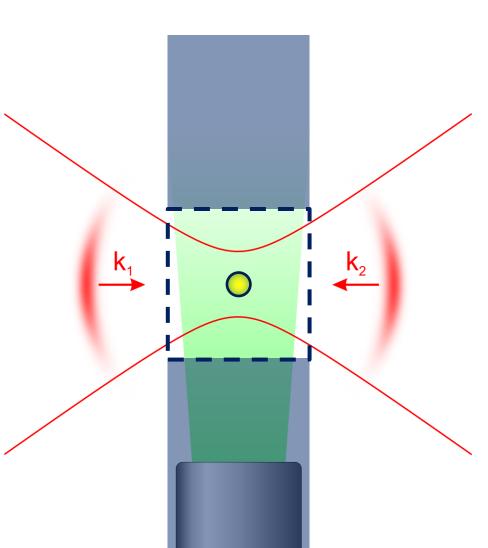

Dephasing, Depletion and Defocusing

- Pulse-front tilted laser enforces vacuum speed of light propagation of laser overlap in plasma.
 - → Circumvents dephasing
- Oblique laser beam geometry continuously feeds a "fresh" portion of the laser beams into an unperturbed plasma.
 - → Averts laser depletion
- Line-focus geometry
 - → Circumvents laser defocusing

Debus et al., Phys. Rev. X 9, 031044 (2019) 10.1103/PhysRevX.9.031044

Practical considerations for energy-scalable Laser-plasma accelerators Advantages of a lateral, non-axially symmetric geometry

Strictly lateral, laser in- and out coupling

- → Stationary propagation distances to center of interaction.

 Geometrically enforces of stationary acceleration conditions.
- → No geometric occlusion from gas nozzle or scrapers.
- → Reduces need to ionize an extended plasma volume compared to axial laser-coupling.
- → Easier accelerator scaling: Subsequent stages can be placed right after one another. Length of stages depends on available lasers.

High-density TWEAC setups at low-incident angle beams (~5°) are an ideal testbed

- High-density plasmas have more pronounced plasma dynamics on smaller spatial and shorter time scales.
- Greatly reduces simulation time for exploring the regime.
- Benefits on controlling dephasing, depletion and diffraction are seen earlier.
- Experimental perspective of proof-of-principle experiments by lower laser energy requirements.
- Speeds up learning curve by exposing potential problems earlier, such as blowing up plasma dynamics, code numerics or both.

$$L_{LWFA,dephasing}(n_e = 10^{19} \text{ cm}^{-3}, a_0 = 3.0) \sim 680 \mu\text{m}$$

 $L_{LWFA,depletion}(n_e = 10^{19} \text{ cm}^{-3}, a_0 = 3.0) \sim 1330 \mu\text{m}$

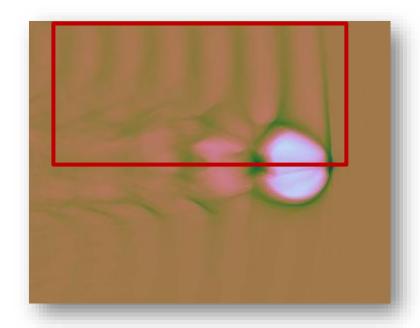

interaction angle φ [°]

Scenario	Non-linear, "bubble-like" plasma cavity	Quasi-linear accelerator at lower intensity
Interaction distance	3cm	3cm
Total laser energy	23.5J / 30fs	~1J / 30fs
laser incidence angle ϕ	3.5°	3.5°
peak laser strength a ₀ in line-focus	5.0	1.0
Acceleration gradient	~1 GeV/cm	0.3 GeV/cm

Maxwell-exact analytic TWEAC laser model required for strong focusing

- Small-angle incidence focusing increases effective laser spot sizes $\mathbf{w}_{\text{eff}} \sim \mathbf{w}_0 / \sin(\Phi)$.
- This can still work for TWEAC scenarios at lower densities <10¹⁹ cm⁻³ or at much larger angles Φ > 5°. However, for matching at high densities 10¹⁹ cm⁻³, $w_{0,eff} \sim 6 \mu m$ is needed.
 - \rightarrow Small w_{0.eff} requires even smaller w₀, i.e. strong focusing required.
 - → Requires strong focusing and paraxial approximation for cylindrical focusing breaks down.
 - → Required new TWEAC laser model for strong focusing.

At small-angle incidence, paraxial TWEAC models over time expose unphysical asymmetries.

Alexander Debus

Maxwell-exact analytic TWEAC laser model for strong focusing

Maxwell-exact model of ultrashort TWEAC pulses

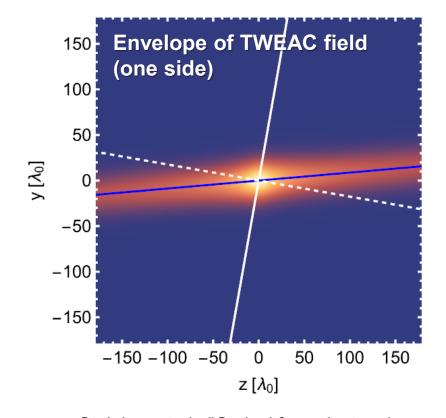

- Includes strong focusing down to the λ scale.
- For all linear polarization angles α.
- For all incident angles Φ.
- Arbitrary comoving foci β₀.
- For all E- and B-fields.

Implemented and tested new laser model in PICon CEU

- Replaced legacy model, based on paraxial approximation.
- New implementation is shorter, faster and more maintainable (>1600 LOCs less).

Derivation

- Based on complex source method combined and a dual-field setup.
- Exploits zero-order cylindrical Bessel-function J₀ to be exact solution of Helmholtz equation.
- Specializes solution for ultrashort pulses with TWEAC-like dispersion properties.
- Exposes a suitable base of linear polarization states for TWEAC lasers.

Resulting E_x – field component in PIConGPU coordinates, i.e. focal axis along y-coordinate

$$E_x(x,y,z,t) = \frac{i}{2k\,\rho_-^3\,I_0\left(\frac{1}{2}k^2\sin\phi\,w_0^2\right)}\,e^{i(\omega_0t-ky\cos\phi)}\,U_{\rm pulse}(\nu,\xi,t)\,\times \\ \left\{k\rho_-\int_{0}^{J_0(k\rho_-\sin\phi)}\left[\left(\rho_-^2-x^2+xX_-\cos\phi\right)\sin\alpha\sin^2\phi\right] \right. \\ \left. \begin{array}{l} {\rm Complex\ valued\ Bessel-functions\ not\ natively\ supported\ for\ GPUs\ by\ CUDA\ or\ HIP\ software\ stacks.} \\ +\cos\alpha\left(\rho_-^2+\rho_-^2\cos^2\phi-x^2\sin^2\phi-xX_-\cos\phi\sin^2\phi\right) \right] \\ +J_1(k\rho_-\sin\phi)\sin\phi\left[\sin\alpha\left(-\rho_-^2+2x^2-ik\rho_-^2X_-\sin\phi+x\cos\phi\left(-2X_--ik\rho_-^2\sin\phi\right)\right)\right. \\ \left. +\cos\alpha\left(-\rho_-^2+2x^2+ik\rho_-^2X_-\sin\phi+x\cos\phi\left(2X_-+ik\rho_-^2\sin\phi\right)\right) \right] \right\} \\ \left. \begin{array}{l} \rho_-=\sqrt{x^2+X_-^2}\\ X_-=-\left(z+\frac{i}{2}kw_0^2\right) \end{array} \right. \\ \left. \begin{array}{l} \lambda_+ \cos\alpha\left(-\rho_-^2+2x^2+ik\rho_-^2X_-\sin\phi+x\cos\phi\left(2X_-+ik\rho_-^2\sin\phi\right)\right) \\ X_-=-\left(z+\frac{i}{2}kw_0^2\right) \end{array} \right\} \\ \left. \begin{array}{l} \lambda_+ \cos\alpha\left(-\rho_-^2+2x^2+ik\rho_-^2X_-\sin\phi+x\cos\phi\left(2X_-+ik\rho_-^2\sin\phi\right)\right) \\ X_-=-\left(z+\frac{i}{2}kw_0^2\right) \end{array} \right. \\ \left. \begin{array}{l} \lambda_+ \cos\alpha\left(-\rho_-^2+2x^2+ik\rho_-^2X_-\sin\phi+x\cos\phi\left(2X_-+ik\rho_-^2\sin\phi\right)\right) \\ X_-=-\left(z+\frac{i}{2}kw_0^2\right) \end{array} \right. \\ \left. \begin{array}{l} \lambda_+ \cos\alpha\left(-\rho_-^2+2x^2+ik\rho_-^2X_-\sin\phi+x\cos\phi\left(2X_-+ik\rho_-^2\sin\phi\right)\right) \\ X_-=-\left(z+\frac{i}{2}kw_0^2\right) \end{array} \right. \\ \left. \begin{array}{l} \lambda_+ \cos\alpha\left(-\rho_-^2+2x^2+ik\rho_-^2X_-\sin\phi+x\cos\phi\left(2X_-+ik\rho_-^2\sin\phi\right)\right) \\ X_-=-\left(z+\frac{i}{2}kw_0^2\right) \end{array} \right. \\ \left. \begin{array}{l} \lambda_+ \cos\alpha\left(-\rho_-^2+2x^2+ik\rho_-^2X_-\sin\phi+x\cos\phi\left(2X_-+ik\rho_-^2\sin\phi\right)\right) \\ X_-=-\left(z+\frac{i}{2}kw_0^2\right) \end{array} \right. \\ \left. \begin{array}{l} \lambda_+ \cos\alpha\left(-\rho_-^2+2x^2+ik\rho_-^2X_-\sin\phi+x\cos\phi\left(2X_-+ik\rho_-^2\sin\phi\right)\right) \\ X_-=-\left(z+\frac{i}{2}kw_0^2\right) \end{array} \right. \\ \left. \begin{array}{l} \lambda_+ \cos\alpha\left(-\rho_-^2+2x^2+ik\rho_-^2X_-\sin\phi+x\cos\phi\left(2X_-+ik\rho_-^2\sin\phi\right)\right) \\ X_-=-\left(z+\frac{i}{2}kw_0^2\right) \end{array} \right. \\ \left. \begin{array}{l} \lambda_+ \cos\alpha\left(-\rho_-^2+2x^2+ik\rho_-^2X_-\sin\phi+x\cos\phi\left(2X_-+ik\rho_-^2\sin\phi\right)\right) \\ X_-=-\left(z+\frac{i}{2}kw_0^2\right) \end{array} \right. \\ \left. \begin{array}{l} \lambda_+ \cos\alpha\left(-\rho_-^2+2x^2+ik\rho_-^2X_-\sin\phi+x\cos\phi\left(2X_-+ik\rho_-^2\sin\phi\right)\right) \\ X_-=-\left(z+\frac{i}{2}kw_0^2\right) \end{array} \right. \\ \left. \begin{array}{l} \lambda_+ \cos\alpha\left(-\rho_-^2+2x^2+ik\rho_-^2X_-\sin\phi\right) \\ X_-=-\left(z+\frac{i}{2}kw_0^2\right) \end{array} \right. \\ \left. \begin{array}{l} \lambda_+ \cos\alpha\left(-\rho_-^2+2x^2+ik\rho_-^2X_-\sin\phi\right) \\ X_-=-\left(z+\frac{i}{2}kw_0^2\right) \end{array} \right. \\ \left. \begin{array}{l} \lambda_+ \cos\alpha\left(-\rho_-^2+2x^2+ik\rho_-^2X_-\sin\phi\right) \\ X_-=-\left(z+\frac{i}{2}kw_0^2\right) \end{array} \right. \\ \left. \begin{array}{l} \lambda_+ \cos\alpha\left(-\rho_-^2+2x^2+ik\rho_-^2X_-\sin\phi\right) \\ \left. \begin{array}{l} \lambda_+ \cos\alpha\left(-\rho_-^2+2x^2+i$$

TWEAC pulse including pulse front tilt and dispersion properties

$$U_{\text{pulse}}(\nu, \xi, t) = \frac{\tau_G \sqrt{\omega_0}}{\sqrt{2\Psi}} \exp\left(-\frac{\omega_0 (t - \nu + \xi)^2}{\Sigma}\right)$$

$$\Psi = \frac{1}{2} \omega_0 \tau_G^2 - i(\nu - \xi) \cot^2 \phi + \frac{i}{\beta_0} (2\nu - \xi) \cot \phi \csc \phi - \frac{i}{\beta_0^2} \nu \csc^2 \phi$$

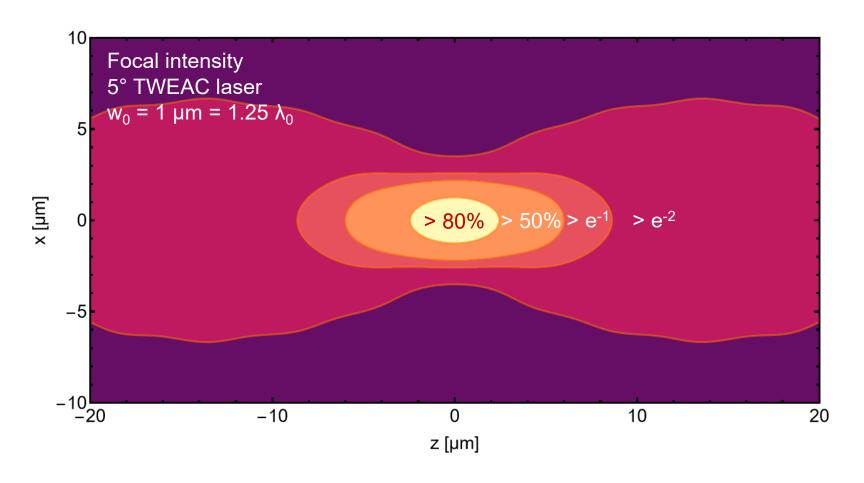

$$\Sigma = \omega_0 \tau_G^2 - 2i(\nu - \xi) \cot^2 \phi + \frac{2i}{\beta_0} (2\nu - \xi) \cot \phi \csc \phi - \frac{2i}{\beta_0^2} \nu \csc^2 \phi$$

$$\nu = \frac{y\cos\phi - z\sin\phi}{c}$$

$$\xi = \frac{\left(\beta_0\cos\phi - 1\right)\left(z\cos\phi + y\sin\phi\right)}{\beta_0c\sin\phi}$$

"Matching" a 5° incidence angle TWEAC pulse to 10¹⁹ cm⁻³ plasma in strong focus geometry

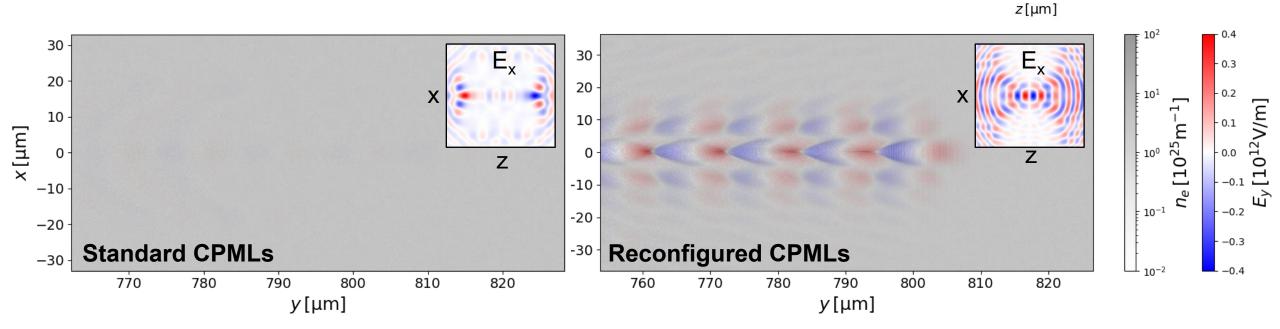

- Plasma wavelength at 10¹⁹ cm⁻³ corresponds to 10.7µm.
- LWFA matching diameter for a₀=3.0 suggests w_{0,eff} = 5.8 μm.
 Fullfills criterion normal to propagation plane.
- In focal-direction, the situation is more complicated and likely not fully described by the LWFA matching criterion.
- TWEAC does not strictly require meeting matching conditions since self-guiding is not needed.

Grazing incidence laser beams are challenging for absorbing boundaries

- Standard perfectly-matched layer (PML) thickness (12 cells) was not enough for 5° incident angle. Very efficient reflection at simulation boundary.
- Increased to 80 cells and reconfigured PML properties to be more susceptible for grazing incidence.
- Supression of reflections still not perfect.

 $E_{x}[10^{12}V/m]$

This is better...

[mm]x

TWEAC is an Exascale challenge

- Typical small test simulation for TWEAC 221 x 111 x 111 µm, 3mm acceleration length 2048x MI250X GPUs, 80 min walltime (compute time w/o output)
- A projected 30 GeV run requires > 100x more

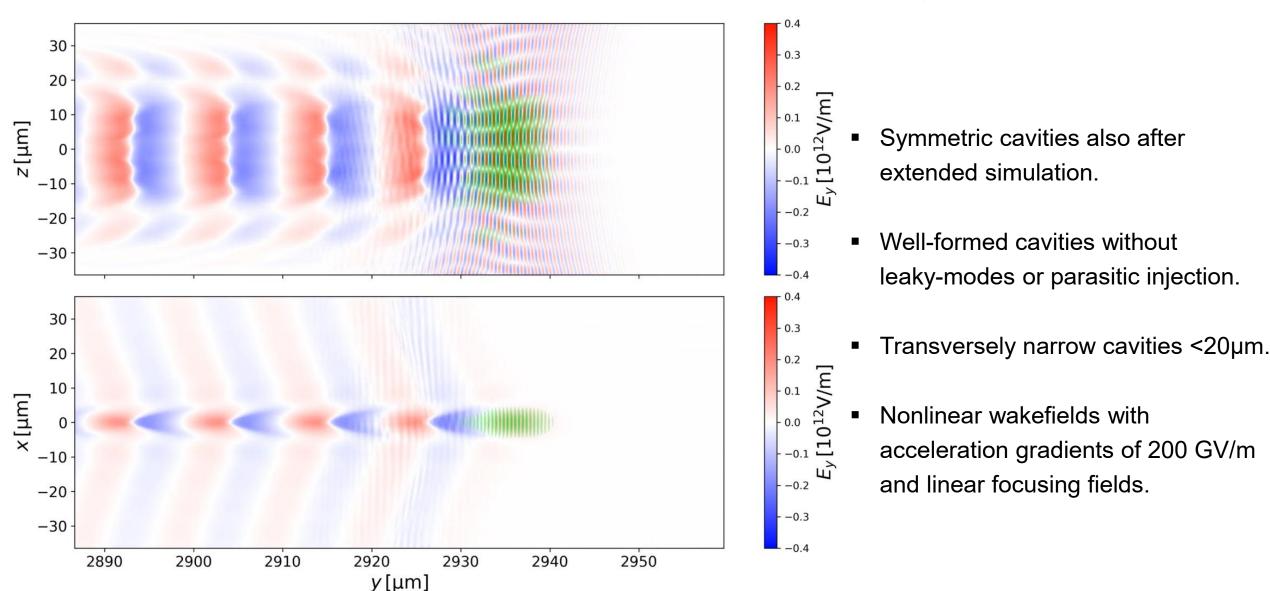

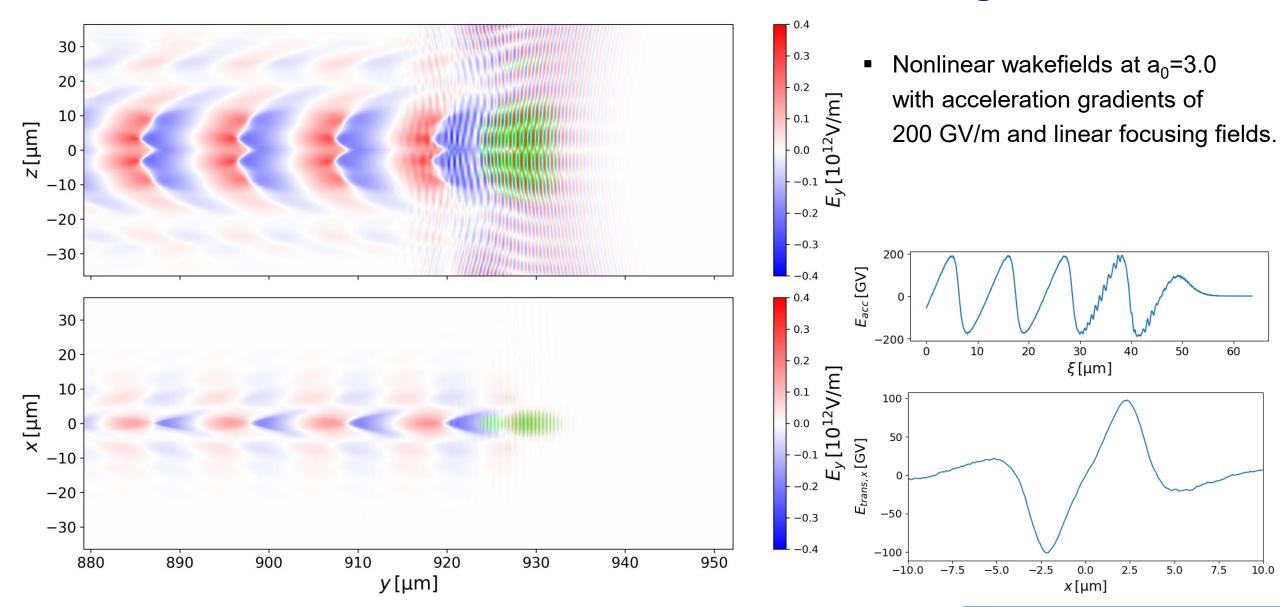

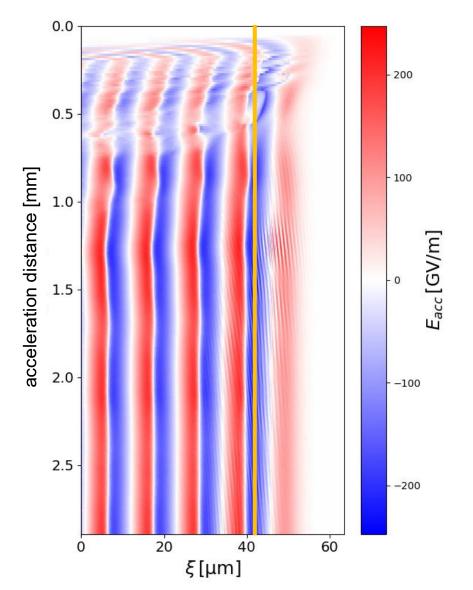

Stationary acceleration conditions for small-angle TWEAC

Acceleration fields reach 200 GV / m acceleration gradients

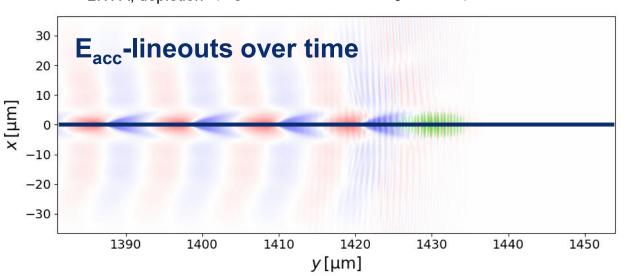

Beyond dephasing – low-angle TWEAC achieves steady state acceleration

- Field reaches steady-state in accelerating field after 0.75 mm and remains constant far beyond LWFA dephasing and depletion lengths.
- Some reflections from boundarie still exist
 → Need to further reduce PML reflections.

$$L_{LWFA, dephasing}(n_e = 10^{19} \text{ cm}^{-3}, a_0 = 2.0) \sim 680 \mu \text{m}$$

 $L_{LWFA, depletion}(n_e = 10^{19} \text{ cm}^{-3}, a_0 = 2.0) \sim 1330 \mu \text{m}$

-0.3

Transverse plasma dynamics shifts TWEAC lateral line foci

- The plasma self-focusing dynamics shifts the TWEAC laser foci.
- This can be precompensated by shifting the initial cylindrical line focus.
- Here, the focal lines have been shifted too much.
- Requires further investigation.

Conclusions

Traveling-wave electron acceleration (TWEAC)

- Circumvents the LWFA diffraction, dephasing and depletion limits.
- Can in principle be arbitrarily extended in a single stage up to the energy frontier.
- Non-axialsymmetric lateral in- and output coupling maintains quasi-stationary accelerator dynamics.
- Simulating TWEAC beyond 10 GeV requires exascale computing resources.

Energy-efficient, low-angle ($\Phi = 5^{\circ}$) TWEAC at high plasma densities (10^{19} cm⁻³)

- Demonstrated stationary acceleration conditions for small-angle TWEAC scenarios beyond dephasing and depletion length.
- For low-incidence angle setups: A new TWEAC laser model, supporting strong focus geometries, enables modeling narrow TWEAC acceleration cavities < 20µm in width.
- Transition to steady-state conditions < 0.7mm.
- Nonlinear TWEAC wakefields support 200 GeV/m.
