We report on a simultaneous study of the  $(p, p)$ ,  $(p, \alpha)$  and  $(p, d)$  reactions on

$^7\text{Li}$  at low energies [1]. The

experiment was performed using a thick hydrogen target and a radioactive

$^7\text{Li}$  beam available at the RIBRAS facility

of S'ao Paulo [2]. This experiment represents an upgrade of a previous experiment [3], where only the

$^7\text{Li}p\alpha$  cross

section was measured. A comparison

with previous direct

$^7\text{Li}dp$  data suggests a newly observed

$^7\text{Li}be$  resonance around  $E_x = 18.67$  MeV with a

large  $^7\text{Li}^* + d$  component. The

properties of this resonance are determined by a  $R$ -matrix analysis [4], which provides evidence for a significant clustering.

As the  $^7\text{Li}^*$  nucleus and the deuteron present a strong deformation, this

$^7\text{Li}be$  state can be

interpreted as a

four-body resonance. We suggest that it could be also observed in

$^7\text{Li}dp$  inelastic scattering.
