• Basic formalism of the GLM Model and other models based on RFT

• Discrepancies in $\sigma_{tot}$ data and lessons learnt

• "Tension" in diffractive data at LHC energies?

• Current Models for Soft Interactions at LHC energies

• Conclusions
The Good-Walker (G-W) formalism, considers the diffractively produced hadrons as a single hadronic state described by the wave function $\Psi_{D}$, which is orthonormal to the wave function $\Psi_{h}$ of the incoming hadron (proton in the case of interest) i.e. $<\Psi_{h}|\Psi_{D}> = 0$.

One introduces two wave functions $\psi_1$ and $\psi_2$ that diagonalize the 2x2 interaction matrix $T$

$$A_{i,k} = <\psi_i \psi_k | T | \psi_{i'} \psi_{k'}> = A_{i,k} \delta_{i,i'} \delta_{k,k'}.$$

In this representation the observed states are written in the form

$$\psi_h = \alpha \psi_1 + \beta \psi_2,$$

$$\psi_D = -\beta \psi_1 + \alpha \psi_2$$

where, $\alpha^2 + \beta^2 = 1$
Good-Walker Formalism-2

The s-channel Unitarity constraints for \((i,k)\) are analogous to the single channel equation:

\[
Im A_{i,k}(s, b) = |A_{i,k}(s, b)|^2 + G_{i,k}^{\text{in}}(s, b),
\]

\(G_{i,k}^{\text{in}}\) is the summed probability for all non-G-W inelastic processes, including non-G-W "high mass diffraction" induced by multi-\(IP\) interactions.

A simple solution to the above equation is:

\[
A_{i,k}(s, b) = i \left( 1 - \exp \left( -\frac{\Omega_{i,k}(s, b)}{2} \right) \right), \quad G_{i,k}^{\text{in}}(s, b) = 1 - \exp \left( -\Omega_{i,k}(s, b) \right).
\]

The opacities \(\Omega_{i,k}\) are real, determined by the Born input.
Good-Walker Formalism-3

Amplitudes in two channel formalism are:

\[ A_{el}(s, b) = i\{\alpha^4 A_{1,1} + 2\alpha^2 \beta^2 A_{1,2} + \beta^4 A_{2,2}\}, \]

\[ A_{sd}(s, b) = i\alpha \beta \{-\alpha^2 A_{1,1} + (\alpha^2 - \beta^2)A_{1,2} + \beta^2 A_{2,2}\}, \]

\[ A_{dd}(s, b) = i\alpha^2 \beta^2 \{A_{1,1} - 2A_{1,2} + A_{2,2}\}. \]

With the G-W mechanism \(\sigma_{el}, \sigma_{sd}\) and \(\sigma_{dd}\) occur due to elastic scattering of \(\psi_1\) and \(\psi_2\), the correct degrees of freedom.
Examples of the Pomeron diagrams that lead to a different source of the diffractive dissociation that cannot be described in the framework of the G-W mechanism. (a) is the simplest diagram that describes the process of diffraction in the region of large mass $Y - Y_1 = \ln(M^2/s_0)$. (b) and (c) are examples of more complicated diagrams in the region of large mass. The dashed line shows the cut Pomeron, which describes the production of hadrons.
What can we learn from past discrepancies in data?

As an example consider the value of $\sigma_{\text{tot}}(p\bar{p})$ at $W = 1.8$ TeV. The earliest measurement was that of the E710 colaboration (N.N. Amos et al) [Phys. Lett. B243,158 (1990)] who found
$$\sigma_{\text{tot}}(p\bar{p}) = 72.1 \pm 3.3 \text{ mb}.$$  

Next was the CDF collaboration (F. Abe et al)[Phys. Rev. D50,5550 (1994)] whose result was
$$\sigma_{\text{tot}}(p\bar{p}) = 80.03 \pm 2.24 \text{ mb}.$$  

The third measurement was by E811 collaboration (C.Avila et al)[Phys. Letts.B537,41 (2002)] who measured
$$\sigma_{\text{tot}}(p\bar{p}) = 72.42 \pm 1.55 \text{ mb}.$$  

The fact that the classical Donnachie-Landshoff model with $\alpha_{IP} = 1.08$ and $\alpha'_{IP} = 0.25$ was consistent with $\sigma_{\text{tot}}(p\bar{p}) \approx 72$ mb cast doubt on the CDF result at the time.

In addition the fits of the COMPETE collaboration also went through the E710 point.
Donnachie and Landshoff fit to $\sigma_{tot}(\bar{p}p)$ pre-LHC

(2) KMR Eur.J.P.,C71, 1617 (2011)
After the publication of the TOTEM results at $W = 7$ TeV

The publication of the TOTEM measurement [G. Antchev et al., Europhys. Lett. 101, 21002 (2013)] caused an "upheaval".

It suggested that $\sigma_{\text{tot}}(pp)$ in the Tevatron-LHC energy range grew FASTER than at lower energies.

This resulted in

- An "overhaul" of existing models e.g Donnachie + Landshoff
- or the suggestion of new parametrization e.g. Ciesielski and Goulianos.

D and L introduced an ADDITIONAL HARD POMERON and used an EIKONALIZED Regge pole model with Pomerons and Reggeons:

The values of the parameters were determined by making a simultaneous fit to pp scattering data and to DIS lepton scattering for low $x$.

Their results can be summarized:

**SOFT POMERON**

$\alpha_S^p = 1.093 + 0.25t$

**HARD POMERON**

$\alpha_H^p = 1.362 + 0.1t$

Coupling strength:

$X_1 = 243.5$

$X_0 = 1.2$

At 7 TeV

$\sigma_{\text{tot}}(\text{soft}) = 91$ mb

$\sigma_{\text{tot}}(\text{hard} + \text{soft}) = 98$ mb
From Donnachie and Landshoff arXiv:1112.2485

ONLY SOFT POMERON

(SOFT + HARD) POMERON
The $\sigma_{tot}^{\pm p}(s)$ cross sections at a $pp$ center-of-mass-energy $\sqrt{s}$ are calculated as follows:

$$
\sigma_{tot}^{\pm p} = \begin{cases}
16.79s^{0.104} + 60.81s^{-0.32} \mp 31.68s^{-0.54} & \text{for } \sqrt{s} < 1.8 \text{ TeV}, \\
\sigma_{tot}^{CDF} + \frac{\pi}{s_0} \left[ \left( \ln \frac{s}{s_F} \right)^2 - \left( \ln \frac{s^{CDF}}{s_F} \right)^2 \right] & \text{for } \sqrt{s} \geq 1.8 \text{ TeV},
\end{cases}
$$

The energy at which ”saturation ” occurs $\sqrt{s_F} = 22$ GeV, and $s_0 = 3.7 \pm 1.5 \text{ GeV}^2$.

Their ”event generator” follows Dino’s ”renormalized Regge-theory” model, and their numbers are based on the MBR-enhanced PYTHIA8 simulation.

There are a number of parametrizations e.g. Block + Halzen and the COMPETE collaboration who have successfully described the $\sigma_{tot}(pp)$ cross section over the whole energy range by using $(\ln s + \ln^2 s)$ terms in addition to the Reggeon term.

Models based on the dipole formalism e.g. Kopeliovich et al have also successfully predicted p-p cross sections. (More details later).

(5) KMR Eur. J. P. C74, 2756 (2014)

Summary of Elastic pp scattering today (borrowed from Peter Skands)
Can anything be learnt from the discrepancy in the $\sigma_{\text{tot}}(pp)$?

- Most models and parametrizations that agree with the TOTEM values for $\sigma_{\text{tot}}$ at the LHC are closer to the CDF value than to the E710 and E811 values at the Tevatron.

- Does this mean that the CDF value is the correct one at $W = 1.8$ TeV?

- Since parameters of the Monte Carlo’s and models are determined by fitting to the available experimental data.

- Their efficacy is determined by the accuracy of the data.

- e.g. The GLM model prior to the LHC measurements had $\alpha_{IP} = 0.21$ and gave a value of $\sigma_{\text{tot}} = 74.9$ mb for $W = 1.8$ TeV.

To be consistent with the TOTEM value measured at $W = 7$ TeV, we needed to increase the Pomeron intercept to $\alpha_{IP} = 0.23$ which increased the value of $\sigma_{\text{tot}} = 79$ mb at $W = 1.8$ TeV and 98.6 mb for $W = 7$ TeV.
E710 measured SD cross section at the Tevatron

E710 made two measurements of $\sigma_{sd}$ at $W = 1.8$ TeV

The first [N.A. Amos et al Phys. Lett. B243,168 (1990)] was a luminosity independent measurement with the result $\sigma_{sd} = 11.7 \pm 2.3$ mb

The second [N.A. Amos et al Phys. Lett. B301,313 (1993)], measured data in the range

$3 < M_X < 200$ GeV and for $0.05 \leq |t| \leq 0.11$ GeV

ASSUMING that $M_X$ and $t$ are INDEPENDENT they EXTRAPOLATED the behaviour of the cross section to all values of $t$, for $2$ GeV $< M_X^2 < 0.05$s yielding a value $\sigma_{sd} = 8.1 \pm 1.7$ mb

Since the two measurements were independent they combined them to give a value $\sigma_{sd} = 9.4 \pm 1.4$ mb

Includes ND background
Comparison of results obtained in GLM, Ostapchenko, K-P, KMR and KPP models.

Ostapchenko (Phys.Rev.D81,114028(2010)) [pre LHC] has made a comprehensive calculation in the framework of Reggeon Field Theory based on the resummation of both enhanced and semi-enhanced Pomeron diagrams.

To fit the total and diffractive cross sections he assumes TWO POMERONS: (for SET C)

"SOFT POMERON" \( \alpha^{Soft} = 1.14 + 0.14t \) "HARD POMERON" \( \alpha^{Hard} = 1.31 + 0.085t \)

The Durham Group (Khoze, Martin and Ryskin) (Eur.Phys.J.C73,2503 (2013)) suggested a TWO channel eikonal model where the Pomeron couplings to the diffractive eigenstates depend on the collider energy. They have four versions of the model. The parameters of the Pomeron of their “favoured version” Model 4 are:

\[ \Delta_{IP} = 0.11; \alpha'_{IP} = 0.06 \text{ GeV}^{-2}. \] I will refer to this as KMR2C.

KMR have recently updated their model ((Eur.Phys.J.C74,2756 (2014)) to be consistent with the TOTEM diffractive data, (energy dependent coupling constants ). I refer to this version as KMR14.

Kaidalov-Poghosyan have a model which is based on Reggeon calculus, they attempt to describe data on soft diffraction taking into account all possible non-enhanced absorptive corrections to 3 Reggeon vertices and loop diagrams. It is a single \( IP \) model and with secondary Regge poles, they have

\[ \Delta_{IP} = 0.12; \alpha'_{IP} = 0.22 \text{GeV}^{-2}. \]
Dipole Approach to Soft Scattering

A two scale structure of the light hadrons was assumed:
- a SOFT scale of the order of the confinement radius \( R_c \approx \frac{1}{\Lambda_{QCD}} \approx 1 \text{ fm} \)
- a SEMI-HARD scale \( \approx 0.3 \text{ fm} \) characterizing non-perturbative interactions of gluons.

This is reflected in their two term expression for the total cross section:

\[ \sigma_{tot} = \text{large constant term (from soft interactions)} + \text{steeply rising term (related to gluon radiation [\( \sim s^{\Delta} \text{ with } \Delta = 0.17 \])} \]

K+P+ Schmidt [Phys.Rev.C73,034901(2006)] have extended the model to proton-nucleus plus

\[ p + p \rightarrow p + X. \]

Their results for \( \sigma_{SD} \) have not been updated to compare with LHC energies.

K + P + Povh [Phys.Rev.D86,051502 (2012)] compare the results of their approach with the TOTEM (LHC) elastic data, and show excellent agreement with the predictions made eleven years previously.

Conclusions

- Experimental measurements of $\sigma_{SD}$ have been made over a limited region of $M_X$ and then EXTRAPOLATED using Monte Carlos to obtain $\sigma_{SD}$ for $\frac{M_X^2}{s} \leq 0.05$

- It appears that there is enough "slack" present in the diffractive data to release any "tension" that there might be.

- My best guess is that for $W = 7$ TeV, the result for single diffractive cross section in the above range of $M_X^2$ is $\sigma_{SD} \approx 10 - 11$ mb.

- The question that is still open:-

  HAVE WE REACHED AN ENERGY REGIME WHERE $\sigma_{SD}$ EXHIBITS A CHANGE IN IT’S BEHAVIOUR FROM THAT AT LOWER ENERGIES?
### Results of GLM model

| \( \sqrt{s} \) TeV | \( \sigma_{\text{tot}} \) mb | \( \sigma_{\text{el}} \) mb | \( \sigma_{\text{sd}}(M \leq M_0) \) mb | \( \sigma_{\text{sd}}(M^2 < 0.05s) \) mb | \( \sigma_{\text{dd}} \) mb | \( B_{\text{el}} \, \text{GeV}^{-2} \) | \( B_{\text{sd}}^{\text{GW}} \, \text{GeV}^{-2} \) | \( \sigma_{\text{inel}} \) mb | \( \frac{d\sigma}{dt}|_{t=0} \, \text{mb/GeV}^2 \) |

Predictions of our model for different energies \( W \). \( M_0 \) is taken to be equal to 200GeV as ALICE measured the cross section of the diffraction production with this restriction.
The total cross section

Energy evolution of $\sigma_{\text{tot}}$

$\sigma_{\text{tot}} = 95.4 \pm 1.4 \text{ mb}$

$\sigma_{el} = 24.0 \pm 0.6 \text{ GeV}^{-2}$

Comparison with TOTEM measurements

Elastic cross section from the integrated fit-function (nuclear part)

$$\sigma_{el} = \frac{\sigma_{\text{tot}}^2}{B} \frac{1 + \rho^2}{16\pi(hc)^2}$$
GLM Formalism

The input opacity \( \Omega_{i,k}(s, b) \) corresponds to an exchange of a single bare Pomeron.

\[
\Omega_{i,k}(s, b) = g_i(b) g_k(b) P(s).
\]

\( P(s) = s^{\Delta_P} \) and \( g_i(b) \) is the Pomeron-hadron vertex parameterized in the form:

\[
g_i(b) = g_i S_i(b) = \frac{g_i}{4\pi} m^3 \gamma K_1(m_i b).
\]

\( S_i(b) \) is the Fourier transform of \( \frac{1}{(1+q^2/m_i^2)^2} \), where, \( q \) is the transverse momentum carried by the Pomeron.

The Pomeron’s Green function that includes all enhanced diagrams is approximated using the MPSI procedure, in which a multi Pomeron interaction (taking into account only triple Pomeron vertices) is approximated by large Pomeron loops of rapidity size of \( \ln s \).

The Pomeron’s Green Function is given by

\[
G_P(Y) = 1 - \exp \left( \frac{1}{T(Y)} \right) \frac{1}{T(Y)} \Gamma \left( 0, \frac{1}{T(Y)} \right),
\]

where \( T(Y) = \gamma e^{\Delta_P Y} \) and \( \Gamma(0, 1/T) \) is the incomplete gamma function.
Fits to the Data

The parameters of our first fit GLM1 [EPJ C71,1553 (2011)] (prior to LHC) were determined by fitting to data

\[ 20 \leq W \leq 1800 \text{ GeV}. \]

We had 58 data points and obtained a \( \chi^2/d.f. \approx 0.86. \)

This fit yields a value of \( \sigma_{tot} = 91.2 \text{ mb} \) at \( W = 7 \text{ TeV}. \)

Problem is that most data is at lower energies (\( W \leq 500 \text{ GeV} \)) and these have small errors, and hence have a dominant influence on the determination of the parameters.

To circumvent this we made another fit GLM2 [Phys.Rev. D85, 094007 (2012)] to data for energies \( W > 500 \text{ GeV} \) (including LHC), to determine the Pomeron parameters. We included 35 data points.

For the present version in addition we tuned the values of \( \Delta_{IP} \), \( \gamma \) the Pomeron-proton vertex and the \( G_{3IP} \) coupling, to give smooth cross sections over the complete energy range

\[ 20 \leq W \leq 7000 \text{ GeV}. \]
Values of Parameters for our updated version

- \( g_1(b) \) and \( g_2(b) \) describe the vertices of interaction of the Pomeron with state 1 and state 2
- The Pomeron trajectory is \( 1 + \Delta_{IP} + \alpha'_{IP} t \)
- \( \gamma \) denotes the low energy amplitude of the dipole-target interaction
- \( \beta \) denotes the mixing angle between the wave functions
- \( G_{3IP} \) denotes the triple Pomeron coupling
What is unique about this version is that it has one pomeron pole, and also includes multi-pomeron interactions with "coupling constants" which decrease with energy due to the growth of $k_T$ of intermediate partons along the $IP$ exchange ladder.

Thus the energy dependence of the cross sections depend on BOTH:

- parameters of the pomeron trajectory
- energy dependence of the proton-pomeron coupling.
