

CMS results on multi-jet correlations

Grigory Safronov
(ITEP, Moscow)

for the CMS Collaboration

Outline

- ✓ **Introduction**
- ✓ **CMS detector**
- ✓ **Datasets**
- ✓ **Measurements**
 - Integrated mini-jet cross-section
 - Inclusive jet production
 - Production of jets with large rapidity separation
- ✓ **Summary**

Physics overview

Integrated mini-jet cross-section

Low p_T (> 1 GeV); probe for pQCD to NP QCD transition as implemented in MC models

Inclusive forward jet cross-section

pQCD benchmark measurement covering large phase space;
an access to $x_1 \ll x_2$

Jets with large rapidity separation

Probes for effects beyond the DGLAP resummation, BFKL

Forward-central dijet production cross-section

Sensitivity to $x_1 \ll x_2$, small- x PDFs

Mueller-Navelet dijet decorrelations

Higher order pQCD contributions at large rapidity intervals

CMS detector

LHC pp runs: $\sim 30 \text{ fb}^{-1}$ collected in 2010 - 2013

- High luminosity was provided by huge bunch intensity
- Huge pileup (PU): up to 20

Pileup is a problem for forward jet or low- p_T measurements

- Jet primary vertex tagging is not possible in forward region

Analyses presented here use 2010 and 2012 data taken at low pileup

- 7 TeV 2010: $\langle \text{PU} \rangle \sim 2.2$, $\mathcal{L} = 44.2 \text{ pb}^{-1}$
- 8 TeV, summer 2012: 2 runs $\langle \text{PU} \rangle \sim 4$, $\mathcal{L} = 5.8 \text{ pb}^{-1}$
- 8 TeV, summer 2012: common CMS + TOTEM run, $\langle \text{PU} \rangle = 0.054$, $\mathcal{L} = 45 \text{ } \mu\text{b}^{-1}$

Measurements

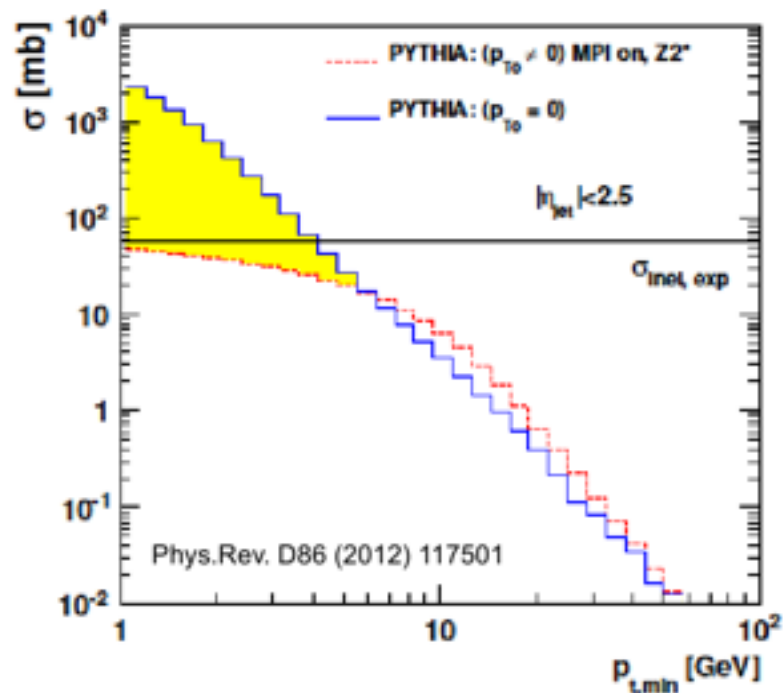

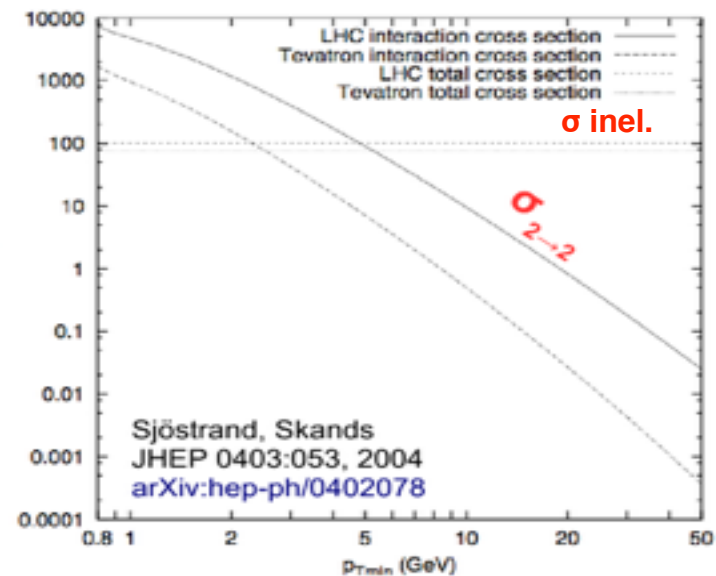

Mini-jet cross-section (I)

Based on Phys. Rev. D86(2012) 117501
(A. Grebenyuk, F. Hautmann, H.Jung, P. Katsas, A. Knutsson)

Total $2 \rightarrow 2$ cross-section is divergent towards low $p_{T,\min}$ (integration threshold, $p_T > p_{T,\min}$) and eventually becomes larger than total inelastic cross-section

At LHC this happens around $p_{T,\min} \sim 5$ GeV

In theory $2 \rightarrow 2$ cross-section needs to be tamed

Pythia, phenomenological parameters:

- Regularisation factor for the cross-section
- Multi-parton interactions

CMS-PAS-FSQ-12-032

Mini-jet cross-section (II)

TOTEM experiment:

T2 telescope

- tracking in the region $5.3 < |\eta| < 6.5$

Common trigger with the CMS - at least one track in **T2**

- 91-96 (%) of total pp inelastic x-sec captured

Common CMS + TOTEM data-taking

- Run with very low pileup at $\sqrt{s} = 8$ TeV (2012), $\langle \text{PU} \rangle = 0.054$, $\mathcal{L} = 45 \mu\text{b}^{-1}$

CMS-PAS-FSQ-12-032

Mini-jet cross-section (III)

Events are triggered by TOTEM T2:

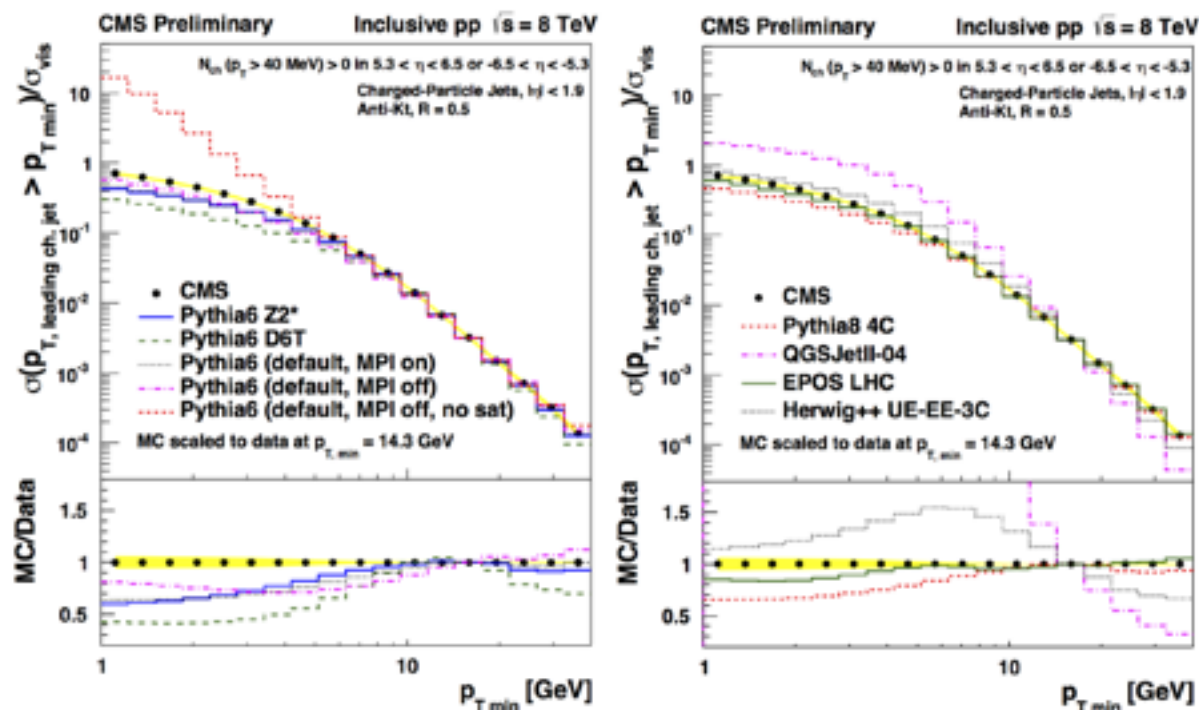

- At least one track $p_T > 40$ MeV, $5.3 < |\eta| < 6.5$

Track-jet selection:

- Charged component, anti- k_T $R=0.5$, $p_T > 1$ GeV, $|\eta| < 1.9$

Event yield as a function of integration threshold $p_{T,min}$ is measured

- And divided by the total number of events

Observations:

- Taming of the cross-section is visible
- Large difference between the models
- Tune sensitivity
- Pythia and Herwig do not describe the data
- Cosmic ray models: **EPOS gives the best description; QGSJet fails**

Inclusive jet cross-section

CMS measurements are performed within $20 \leq p_T \leq 2000$ (GeV) and $|y| < 4.7$

- Combined low-PU runs (Summer 12, $\langle \text{PU} \rangle \sim 4$, $\mathcal{L} = 5.8 \text{ fb}^{-1}$) and full 2012 dataset ($\mathcal{L} = 10.7 \text{ fb}^{-1}$)

Data is well-described by NLO calculations with NP corrections

Forward jet cross-section

Closer look at forward jets:

- $3.2 < |\eta| < 4.7$
- $21 < p_T < 80$ (GeV)

Experimental uncertainties:

- Jet energy scale (JES): $< 45\%$
- Unfolding: $3\text{-}6\%$
- Luminosity: 4%

All predictions agree with data within the uncertainties

Inclusive jet production is well-described by $\text{NLO} \otimes \text{NP}$ predictions over the wide range of p_T and rapidity

Jets with large rapidity separation

pQCD resummation \rightarrow parton showers (PS)

DGLAP PS regime:

$$\sqrt{s} \sim p_T > \Lambda_{\text{QCD}}$$

Strong ordering of emissions in p_T

Measure high- p_T leading jets

BFKL PS regime (QCD high energy limit):

$$\sqrt{s} \gg p_T > \Lambda_{\text{QCD}}$$

Strong ordering of emissions in y

Random walk of emissions in p_T

Measure low- p_T jets with large rapidity span (Δy) \rightarrow approach BFKL limit and open the phase space for multiple emissions with similar p_T

BFKL prediction:
$$\hat{\sigma} \sim \hat{s}^A \sim e^{A\Delta y}, A > 1$$

Search for beyond-DGLAP effects in low- p_T PS with large rapidity span

“low- p_T ” means as low as allowed by the trigger and reconstruction techniques (~ 30 GeV)

Forward-Central jet production (I)

2010 pp runs (low PU), 3.2 pb⁻¹

Measure simultaneous production of forward and central jets

- $p_T > 35$ GeV
- central : $|\eta| < 2.8$
- forward: $3.2 < |\eta| < 4.7$
- p_T - ordering of jets in each region

Absolute differential cross-section

- Leading exp. uncertainty:
JES - up to 50%

Cross-section in p_T bins for intermediate jets

- Good agreement of MC predictions with data

CMS-PAS-FSQ-12-008

Forward-Central jet production (II)

CMS-PAS-FSQ-12-008

Cross-section differential in forward-central azimuthal angle difference, $\Delta\phi$
- In bins of rapidity separation

Herwig and Pythia predictions agree with data within the uncertainty

Mueller-Navelet jet production

Mueller-Navelet (MN) jets – jet pair with similar p_T ($k_1 \sim k_2$) and large rapidity separation

2010 data (low PU), 5 pb^{-1}

Selections:

- Require single primary vertex ($\sim 1/3$ of 2010 data)
- Calorimeter **jet $p_T > 35$ GeV, $|\eta| < 4.7$**
- Rapidity separation coverage of the measurement: **$\Delta y < 9.4$**
 - Combination of inclusive and forward-backward jet triggers

Systematic uncertainties:

- Dominated by JES and unfolding uncertainties, small compared to absolute cross-section measurements
- Pileup influence is reduced (or even removed) by single vertex requirement

Dijet production ratio

Direct probe for higher order radiation:

$$R^{\text{incl}} = \sigma^{\text{incl}} / \sigma^{\text{excl}}$$

“exclusive” - events with exactly two jets above the threshold

Significant spread between models:

- **Best description of the ratio is given by PYTHIA6 and PYTHIA8**
- Herwig++ shows larger growth with increase of rapidity separation
- **BFKL - inspired models CASCADE and HEJ overestimate the data**

MN azimuthal decorrelations

Measurement at D0 in 1996

[10.1103/PhysRevLett.77.595]

$\Delta\eta < 6.0$, $E_T > 50$ (20) GeV

LL BFKL overestimates decorrelation

HERWIG6 gives the best description

CMS measurement

Extends to $\Delta y < 9.4$

Symmetric $p_T > 35$ GeV

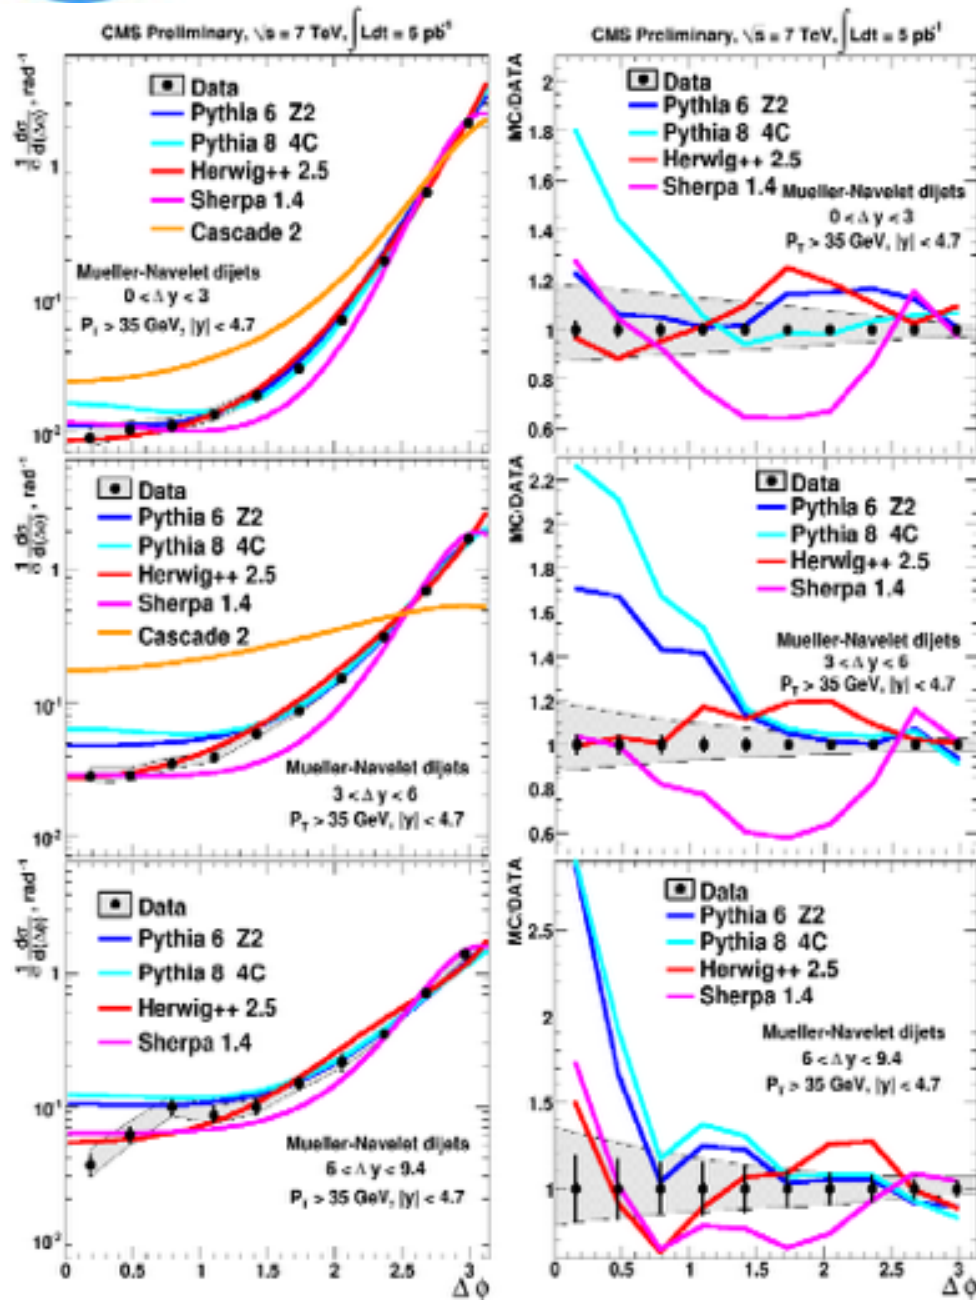

Observables:

- Azimuthal angle separation $\Delta\phi$ in Δy bins
- Average cosines C_1 , C_2 , C_3 as a function of Δy
- Ratios C_2/C_1 , C_3/C_2

$\Delta\phi$ shapes

In $2 \rightarrow 2$ scattering jets are back-to-back and $\Delta\phi = \pi$

Decorrelation is due to higher order radiation

PYTHIA6 and PYTHIA8 show too strong decorrelation

SHERPA underestimates decorrelation

HERWIG++ gives the best description

Average cosines (I)

First 3 coefficients of Fourier transform of $\Delta\phi$ distribution

Equal to average cosines: $C_n = \langle \cos(n(\pi - \Delta\phi)) \rangle$

BFKL NLL predictions at parton level provided by:

B. Ducloué, L. Szymanowski, S. Wallon, [\[10.1007/JHEP05\(2013\)096\]](#)

- Later calculation is available which shows better agreement ([arXiv:1309.3229](#))

C1

Average cosines (II)

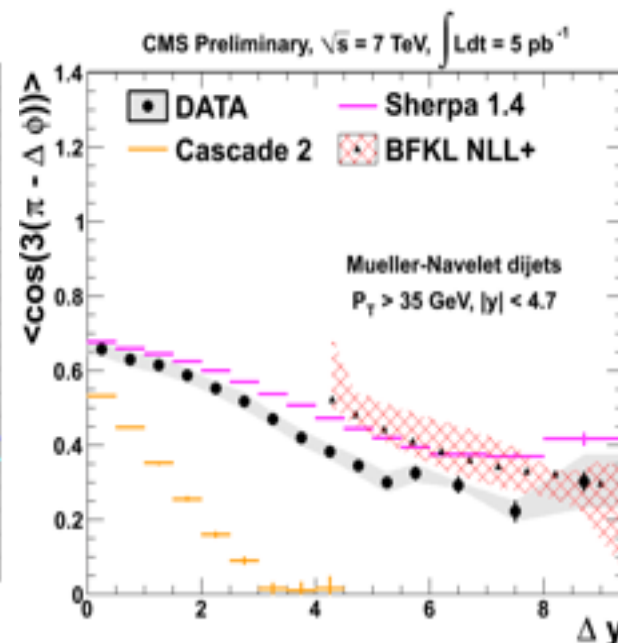

C2

Correlation in SHERPA is stronger than in data

PYTHIA and HERWIG describe the data well

C3

CMS-PAS-FSQ-12-002

Cosine ratios

Ratios of cosines as proposed in
[10.1016/j.nuclphysb.2007.03.050](https://arxiv.org/abs/10.1016/j.nuclphysb.2007.03.050)

(A. Sabio Vera, F. Schwennsen)

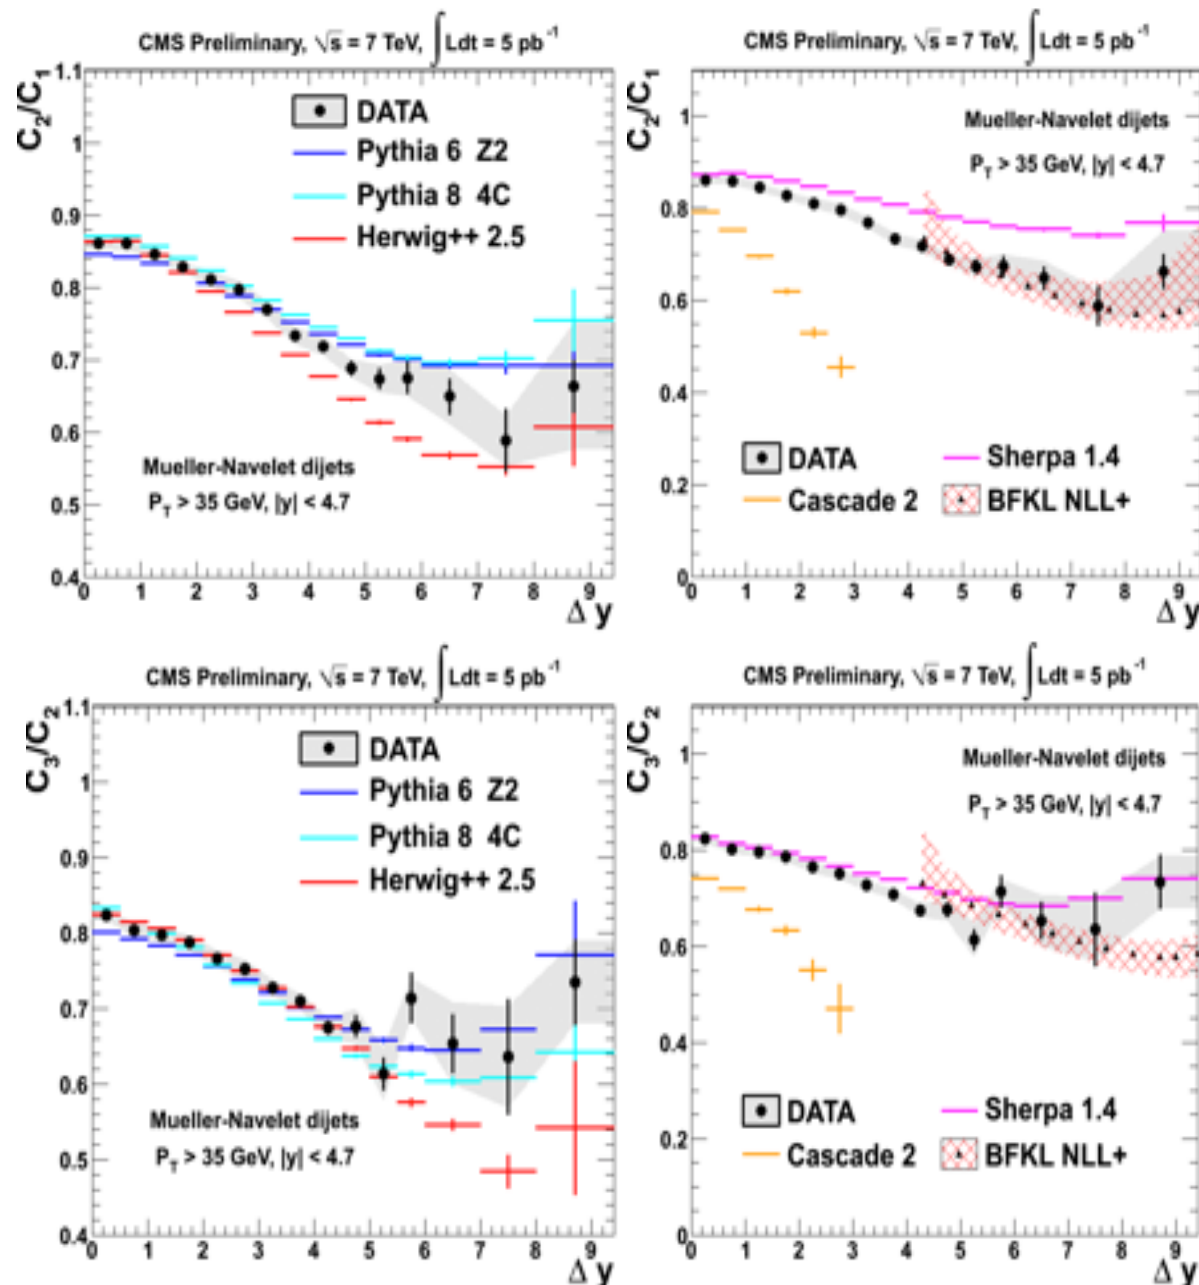

- C_2/C_1 , C_3/C_2

Not conclusive for PYTHIA6, 8 and
 HERWIG++

SHERPA overestimates C_2/C_1 ,
 Consistent with C_3/C_2

**NLL BFKL is consistent with
 ratios**

CMS-PAS-FSQ-12-002

MN azimuthal decorrelations, summary

- ✓ MN azimuthal decorrelations were measured up to $\Delta y = 9.4$
- ✓ Diversity in MC predictions:
 - ✓ None of MC models describe all observables
 - ✓ Best combined description among MC is given by HERWIG++
 - ✓ PYTHIA6, PYTHIA8 and SHERPA show worse agreement
- ✓ Analytic predictions: Data is well-described by NLL BFKL calculations from two groups of authors (not on CMS plots yet)

10.1103/PhysRevLett.112.082003,
arxiv:1309.3229
(B.Ducloe, L. Szymanowski, S. Wallon)

arXiv:1407:8431
(F. Caporale, D.Yu. Ivanov, B. Murdaca, A. Papa)

Minijet cross-section

Most of MC fail to describe the data. Best description is given by cosmic ray model EPOS

Inclusive jet production

Data is well described by $\text{NLO} \otimes \text{NP}$ over the wide p_T and rapidity range

Forward-central jets

PYTHIA and HERWIG provide good description of the data

Mueller-Navelet jets

Inclusive to exclusive dijet production ratios

- PYTHIA6 and PYTHIA8 predictions are within the experimental uncertainties
- HERWIG++, HEJ, CASCADE predict too strong parton radiation

Mueller-Navelet jets angular decorrelations

- No DGLAP-based MC prediction describing all observables
- Analytic NLL BFKL predictions provide better description of the data

BACKUP

Datasets (I)

LHC pp runs: $\sim 30 \text{ fb}^{-1}$ collected in 2010 - 2013

pp data at 7, 8 and 2.76 TeV

Jet reconstruction

Several jet reconstruction techniques

- Calorimeter jets
- “Jet Plus Track” jets
- Particle Flow jets

Anti- k_T , $R=0.5$ or 0.7 clustering algorithm

MC- and data-driven Jet Energy Scale (JES) calibration techniques

- Uncertainty of calibration $< 5\%$ for high- p_T jets
- Uncertainty for low- p_T jets can be as high as 10%

JES uncertainty – leading source of experimental uncertainty

Jet triggers

Jet triggers are based on uncorrected calorimeter energy deposits

Lowest available trigger threshold $p_T > 15$ GeV

- Turn-on point depends on η and type of the jet
- **99% efficiency in full acceptance for calojets with $p_T > 35$ GeV**

Presented analyses use triggers requiring one or two jets with uncorrected ET > 15 GeV

Dijet production ratios

Measurement of dijet production cross-section ratios as a function of rapidity separation

$$R^{\text{incl}} = \sigma^{\text{incl}} / \sigma^{\text{excl}}$$

σ^{excl} - veto on additional jets above the threshold in the event

σ^{incl} - inclusive selection, all pairwise combinations

Properties of observables:

- ✓ Ratio emphasizes higher orders enhanced by $(\alpha_s \Delta y)^n$ in the BFKL limit
- ✓ Remove PDF contributions
- ✓ Experimental systematic uncertainties are decreased
