Abstract

The TOTEM experiment is devoted to the measurement of the proton-proton elastic and total cross section at LHC. It is composed of three detector using different technologies. The TOTEM detector that will measure the inelastic rate in the pseudo-rapidity region $3.1 \le |\eta| \le 4.7$, named T1, is made of Cathode Strip Chambers. Signals from about 11000 anodes and 16000 cathodes must be processed and optically transmitted to the counting room. The complete electronic readout chain of the Cathode Strip Chambers is presented here: the anode and cathode front-end boards, and the readout-control card. The electronics system has been developed keeping into account the hostile environment from the point of views of both radiation and magnetic field. Dedicated VLSI circuits have been extensively used in order to optimize space and power consumption.

The Detector

The T1 telescope, installed in two cone-shaped regions in the end-caps of CMS, delimited by the beam pipe and the inner envelope of the flux return yoke of the magnet, detects charged particles in the pseudo-rapidity range $3.1 \le |\eta| \le 4.7$.

Each telescope arm consists of five planes of CSC equally spaced in z at a distance between 7.5 m and 10.5 m from the interaction point. Each detector plane is composed of six trapezoidal CSC covering roughly a region of 60° in ϕ .

Each telescope arm is built in two vertically divided halves (half arms), in order to allow the installation and removal of T1 when the vacuum chamber is in place.

On Detector Region

The orientation of the cathode strips and of the anode wires provides three measured coordinates of the position of each hit in the CSC plane, useful to reduce the number of fake hits from random combinations ("ghosts") in case of multiple hits. The CSC anode and cathode signals are collected by custom designed anode front-end cards (AFEC) and cathode front-end cards (CFEC), equipped with a custom ASIC called **VFAT** designed at CERN by the TOTEM collaboration.

Electronic system architecture

The AFEC is the board that collects and groups signals from the anode wires of the \neq CSC detector. Ten different types of AFECs have been adapted to the chamber shapes, for a total of 60 boards for the whole detector. The **CFEC** is the board that collects and

VFAT hybrid

"Hits" and information. The VFAT has 128 channel inputs.

Each channel contains a low noise preamplifier and shaper followed by a comparator. Following the comparator are the digital circuits used for generating the "Fast-OR" outputs, data storage and data packet construction.

groups the charge pulses induced in the CSC strips by the positive ions created by the crossing particle and moving towards the cathode. Each board processes 128 input signals.

Read-out system block diagram

Three logically and physically separated regions define the electronic system architecture. The "On Detector Region" where the Front-End ASICs are located, the "Local Detector Region" where the data are collected and optically transmitted to the "Counting Room Region".

Path

Data

Path

The serial digital data stream and the trigger bits coming from the AFEC and CFEC are collected by a custom designed Read-Out Card (**ROC**), where they are serialized and optically transmitted to the DAQ system by means of a dedicated CMS Gigabit Hybrid (**GOH**). The Optical configuration and monitoring of the system is performed using the I²C standard protocol distributed through the optical CMS Slow Control Ring, based on the Digital Opto-Hybrid Mezzanine (DOHM) the and

Conclusions

The TOTEM T1 detector electronics system is fully integrated within the TOTEM DAQ and also fully compatible with CMS DAQ requirements. Prototypes have proven to comply with the required functionalities and performances. The complete set of boards necessary to equip the T1 detector have been built, tested and are ready to be mounted on the detector.
