

Can very compact ***and*** very massive neutron stars both exist?

or

Deltas, hyperons, quarks and all those «exotica»

Alessandro Drago (Ferrara)

Andrea Lavagno (Torino Politecnico)

Giuseppe Pagliara (Ferrara)

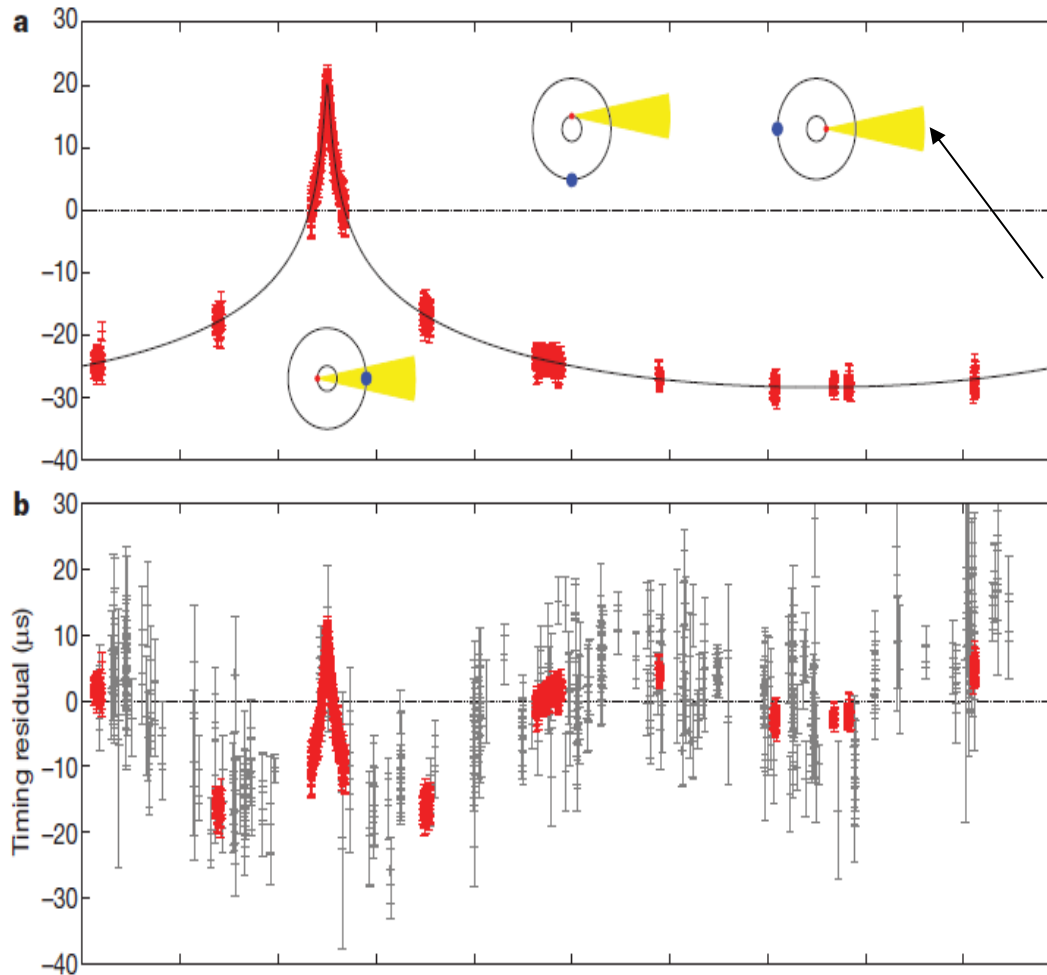

Daniele Pigato (Torino Politecnico)

- Low density behaviour is now rather under control
- At which densities «exotic» degrees of freedom need to appear?
- Hyperons: too much softening?
- What about Δ resonances?
- Are hybrid stars a realistic solution?
- The two-families solution
- The role of the radius in determining the composition: three main possibilities

A milestone for neutron stars physics: PSR J1614-2230, $M = (1.97 \pm 0.04) M_{\text{sun}}$
Demorest et al. Nature 2010

Nuclear and subnuclear densities: symmetry energy

Hebeler et al. 2013

$$S_v = \frac{1}{8} \frac{\partial^2 \epsilon(\bar{n}, x)}{\partial x^2} \Big|_{\bar{n}=1, x=1/2}$$

$$L = \frac{3}{8} \frac{\partial^3 \epsilon(\bar{n}, x)}{\partial \bar{n} \partial x^2} \Big|_{\bar{n}=1, x=1/2}$$

Stars with a normal crust: «possible» Equations of State

Hebeler et al. 2013

a stiff EOS (maybe purely nucleonic)

$$\Gamma_1 = 4.5, \rho_{12} = 1.5 \rho_0, \Gamma_2 = 5.5, \rho_{23} = 2.0 \rho_0, \Gamma_3 = 3.0$$

$$\rho_{\max} = 3.3 \rho_0$$

an intermediate EOS

(maybe hyperonic or hybrid)

$$\Gamma_1 = 4.0, \rho_{12} = 3.0 \rho_0, \Gamma_2 = 3.0, \rho_{23} = 4.5 \rho_0, \Gamma_3 = 2.5$$

$$\rho_{\max} \approx 5.4 \rho_0$$

a soft EOS (NO physical realizations)

$$\Gamma_1 = 1.5, \rho_{12} = 2.5 \rho_0, \Gamma_2 = 6.0, \rho_{23} = 4.0 \rho_0, \Gamma_3 = 3.0$$

$$\rho_{\max} \approx 7.0 \rho_0.$$

Hyperons in compact stars

Few experimental data allow to fix some of the interactions parameters.

Fig. 2. Mass radius relations for neutron stars obtained with the EoS from Fig. 1. The variation of $U_{\Sigma}^{(N)}$ in “model $\sigma\omega\rho$ ” cannot account for the observed neutron star mass limit (lower branch), unless the ϕ meson is included in the model (upper branch).

The 2Msun limit could be fulfilled within RMF models but not in microscopic calculations

Vidana et al 2011

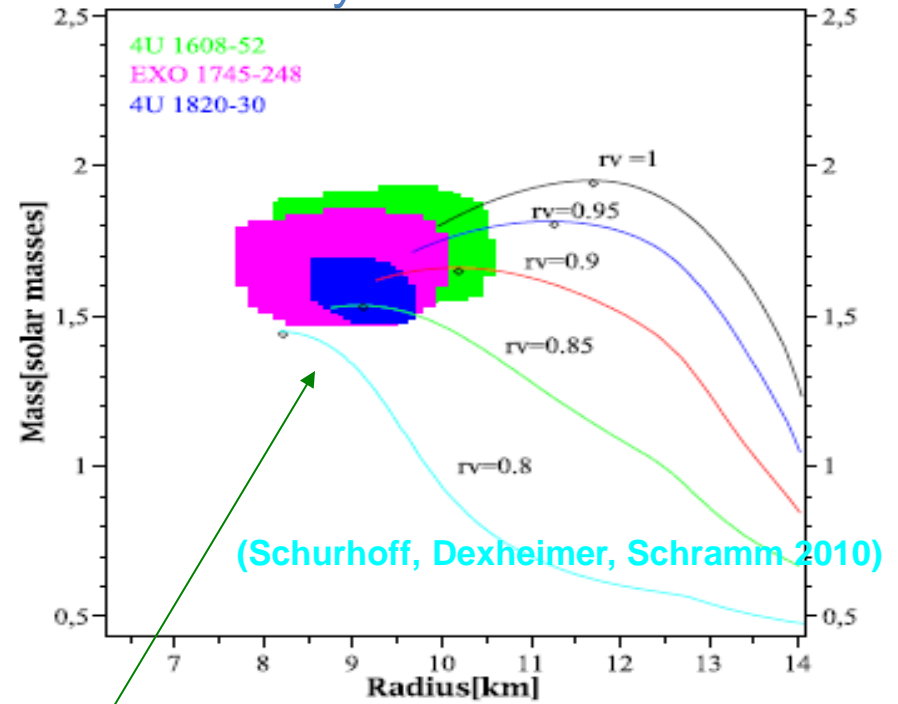

Baldo et al 2000

What about Δ 's?

Here only Δ are included

**Similar effects:
softening of the equation of state.
Small changes of the
couplings with vector mesons
sizably decrease the
maximum mass**

Notice: very small radii

Some constraints on the couplings
with mesons from nuclear matter properties,
electron scattering on nuclei
and QCD sum rules

The appearance of Δ 's shifts the hyperon's thresholds to higher densities

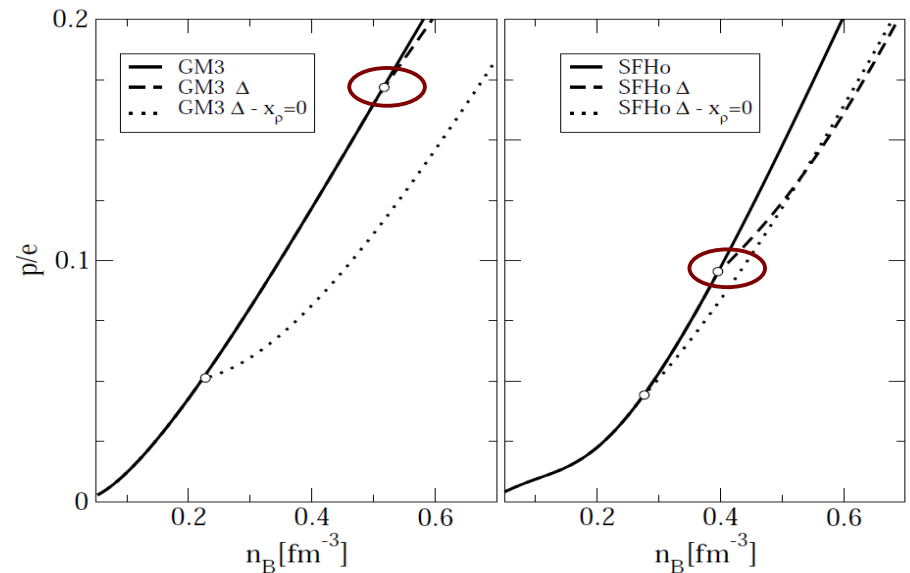

Why Δ s have been neglected so far? (within RMF models)

In Glendenning-Moskowsky models (large L) they appear after the hyperons and are therefore irrelevant (Δ^- is electric charge favored but isospin unfavoured).

In more recent RMF parameterizations (with non-linear terms for the vector mesons), such as SFHo (Steiner, Fischer & Hempel 2013) where new constraints on the symmetry energy are implemented, Δ s appears before hyperons.

The lower value of L implies a smaller effective coupling with the ρ meson.

Struggling with hybrid stars

Ippolito et al. Phys.Rev. D77 (2008) 023004

Zdunik and Haensel A&A, 551 (2013) A61

It is not impossible to satisfy the $2 M_{\odot}$ limit with a hybrid star but special limits on the parameters' values have to be imposed

Radius of a $1.4 M_{\odot}$ hybrid star 12-14 km

Stars containing quark matter?

Alford et al Nature 2006

Kurkela et al 2010

pQCD calculations: “ ... equations of state including quark matter lead to hybrid star masses up to $2M_{\odot}$, in agreement with current observations.

For strange stars, we find maximal masses of $2.75M_{\odot}$ and conclude that confirmed observations of compact stars with $M > 2M_{\odot}$ would strongly favor the existence of stable strange quark matter”

Before the discoveries of the two $2M_{\text{sun}}$ stars!!

... is this surprising?

Heavy ions physics:

(Kolb & Heinz 2003)

Also at finite density the quark matter equation of state should be stiffer than the hadronic equation of state in which new particles are produced as the density increases

Fig. 1. Equation of state of the Hagedorn resonance gas (EOS H), an ideal gas of massless particles (EOS I) and the Maxwellian connection of those two as discussed in the text (EOS Q). The figure shows the pressure as function of energy density at vanishing net baryon density.

$p=e/3$ massless quarks

Hadron resonance gas $p=e/6$

Two families of compact stars:

- 1) low mass (up to $\sim 1.5 M_{\text{sun}}$) and small radii (down to 9-10km) stars are hadronic stars
- 2) high mass and large radii stars are strange stars

Why conversion should then occur?
Quark stars are more bound:
at a fixed total baryon number
they have a smaller gravitational
mass wrt hadronic stars.

The hadronic stars are stable
till when some strangeness
component (e.g. hyperons)
starts appearing in the core.
Only at that point quark matter
nucleation can start.

Finite size effects (surface tension)
can further delay the formation
of the first droplet of strange matter

Nice, but just nucleons,
And it violates causality!

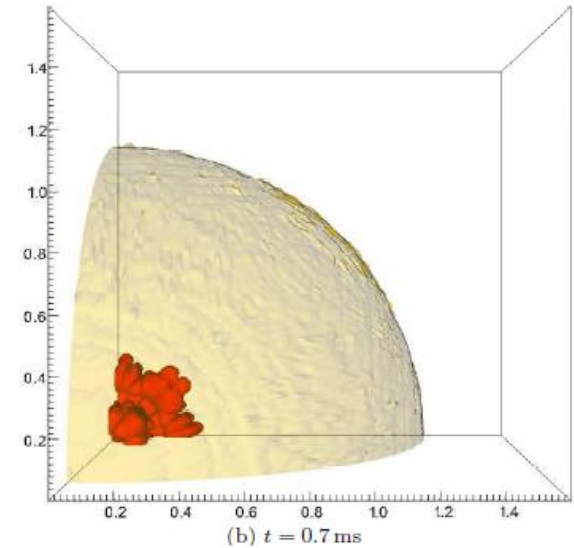

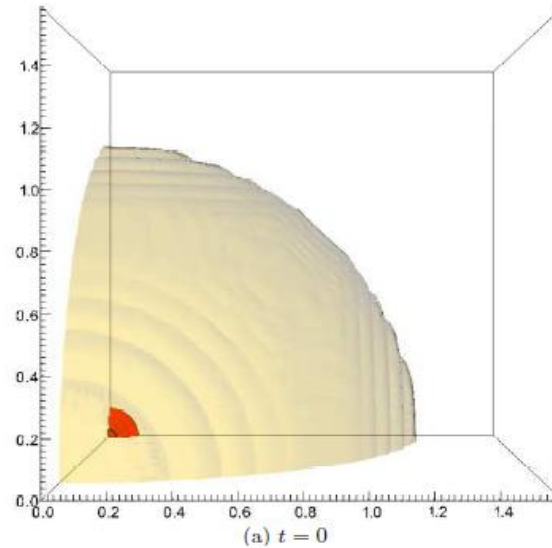

Guillot et al. ApJ772(2013)7
analysis of 5 QLMXBs

Conversion of a 1.4 Msun star

Rayleigh-Taylor instabilities develop and the conversion occurs on time scales of ms.

The burning stops before the whole hadronic matter has converted (the process is no more exothermic, about 0.5 Msun of unburned material)

Herzog, Roepke 2011, G.P. Herzog, Roepke 2013

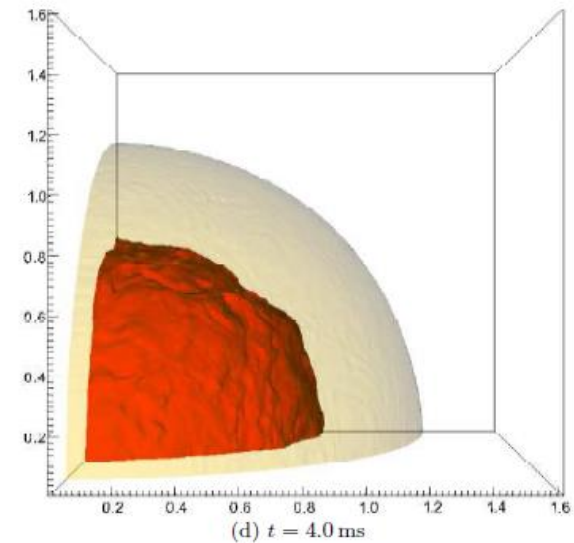

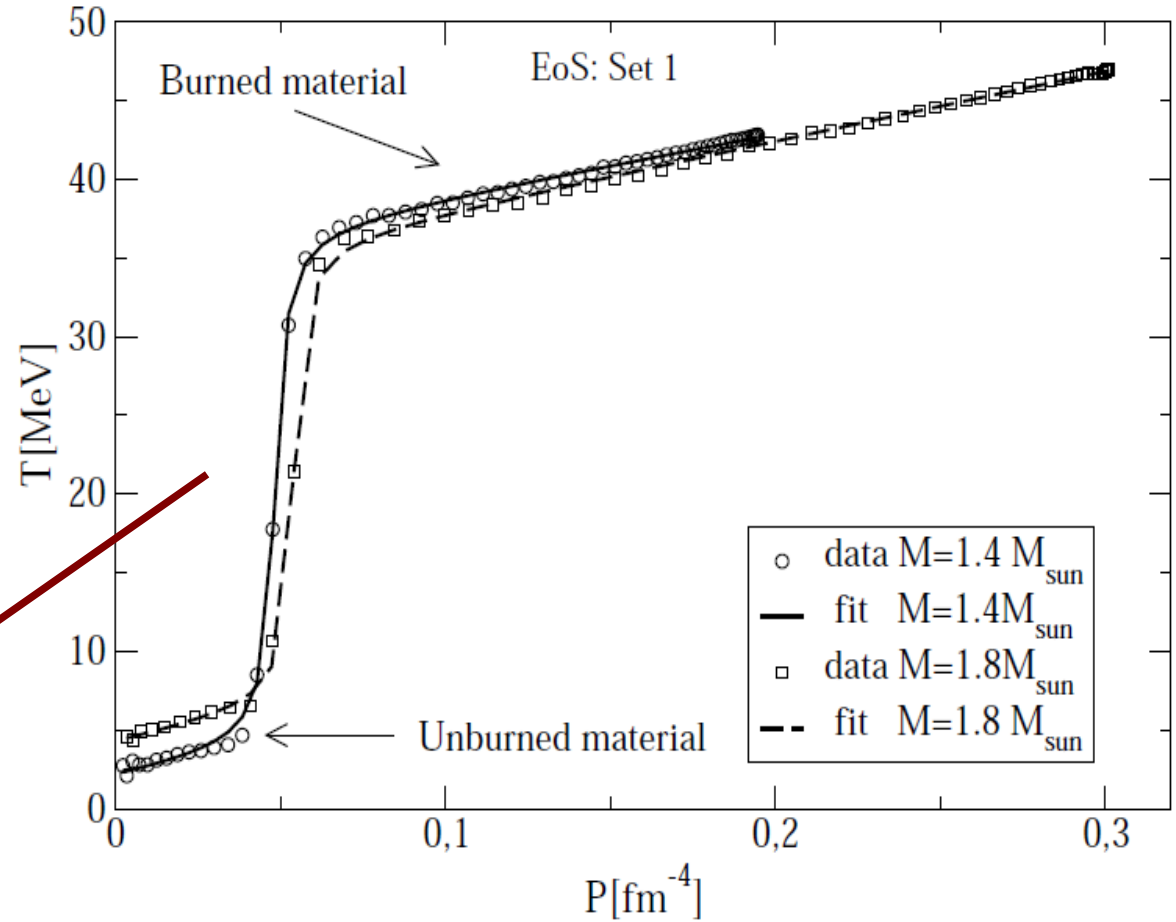

FIG. 1: (color online) Model: Set 1, $M = 1.4M_{\odot}$. Conversion front (red) and surface of the neutron star (yellow) at different times t . Spatial units 10^6 cm.

Temperature profiles after the combustion

The huge energy released in the burning significantly heats the star, up to temperatures of a few tens of MeV in the center.

Steep gradient of the temperature

Luminosity curves similar to the protoneutron stars neutrino luminosities.

The (partial) burning of the more external layers can originate a prolonged neutrino emission, not included in this figure

Possible phenomenology:
GRBs with a double burst
(maybe within the protomagnetar
model of Bucciantini and Metzger)

UNUSUAL CENTRAL ENGINE ACTIVITY IN THE DOUBLE BURST GRB 110709B

Draft version January 17, 2012

ABSTRACT

The double burst, GRB 110709B, triggered *Swift*/BAT twice at 21:32:39 UT and 21:43:45 UT, respectively, on 9 July 2011. This is the first time we observed a GRB with two BAT triggers. In this paper, we present simultaneous *Swift* and *Konus-WIND* observations of this unusual GRB and its afterglow. If the two events originated from the same physical progenitor, their different time-dependent spectral evolution suggests they must belong to different episodes of the central engine, which may be a magnetar-to-BH accretion system.

Subject headings: gamma-ray burst: general

Summary

- Delta resonances can appear before hyperons, shifting the hyperon threshold to larger densities.
- This does NOT solve the hyperonic puzzle, since also Δ resonances make the EOS soft, but it can help in having a physically consistent two-families solution:
low mass – hadronic stars; high mass – quark stars.
- The production of strangeness would be the trigger to the transition to deconfined quark matter and therefore to quark stars.
- Rich phenomenology, specially in relation to explosive phenomena.

New masses and radii measurements challenge nuclear physics:
tension between high mass and small radii. A 2.4 Msun candidate already exists.

New missions (LOFT?, NICER), with a precision of 1km in radii measurements,
could possibly confirm the existence of very compact stars.
