Introduction

- History of UHECR propagation studies
- Protons or nuclei?

Modelling issues

- Monte Carlo simulation codes
- Poorly known quantities ($\sigma_{\rm disi}$ and EBL) and their effects
- 3 Fitting source models to the data
- 4 Conclusions and future directions

Introduction

- History of UHECR propagation studies
- Protons or nuclei?

Modelling issues

- Monte Carlo simulation codes
- Poorly known quantities (σ_{disi} and EBL) and their effects
- 3 Fitting source models to the data
- 4 Conclusions and future directions

Prehistory

- 1911 V.F. Hess discovers cosmic rays
- 1931 G. Lemaître proposes the Big Bang model, but most people continue to believe in the Steady State model
- 1948 R.A. Alpher and R. Herman predict the Big Bang would result in a cosmic microwave background (CMB)
- 1962 Volcano Ranch detects a cosmic ray with $E > 10^{20}$ eV

Empty space is not empty: the GZK effect

- 1965 A.A. Penzias and R.W. Wilson accidentally discover the CMB, confirming the Big Bang model
- 1966 K. Greisen, G.T. Zatsepin and V.A. Kuz'min realize that $p + \gamma_{CMB} \rightarrow p + \pi^0$ and $p + \gamma_{CMB} \rightarrow n + \pi^+$ set a limit ($\approx 10^{20}$ eV) to the energy of protons reaching us from distant sources

What do we see?

- 1998 AGASA observes a power-law spectrum of cosmic rays with no cutoff up to $2\times 10^{20}~\text{eV}$
- 2007 HiRes and the Pierre Auger Observatory do see a high-energy suppression in the cosmic ray spectrum
- Today No other experiment has confirmed the AGASA result, though Auger and Telescope Array disagree about the position of the cutoff

Protons or nuclei?

• Auger data suggest CRs between $10^{19.5}$ and 10^{20} eV mostly nuclei with $A \approx 14$ (but TA data also compatible with protons)

(In the rest of this work, we will only consider Auger data.)
This changes the possible interpretations of the observed cutoff

7/26

Photodisintegration and Gerazimova-Rozental' limit

- Pion production threshold *A* times that for protons but photodisintegration also possible: ${}^{A}Z + \gamma_{\text{CMB or EBL}} \rightarrow {}^{A-1}Z + n$, etc.
- Very short mean free path (especially for light nuclei)
- Secondary nucleons produced with energy *E*/*A*

Introduction

- History of UHECR propagation studies
- Protons or nuclei?

Modelling issues

- Monte Carlo simulation codes
- Poorly known quantities ($\sigma_{\rm disi}$ and EBL) and their effects

Fitting source models to the data

4 Conclusions and future directions

Simulations of UHECR propagation

Monte Carlo codes developed to simulate UHECR propagation, taking into account:

- Adiabatic redshift energy loss (expansion of the Universe)
- Pair production, $N + \gamma_{\text{CMB}} \rightarrow N + e^+ + e^-$
- Disintegration, ${}^{A}Z + \gamma_{\text{CMB or EBL}} \rightarrow {}^{A-1}Z + n$, etc.

• Pion production, $p + \gamma_{CMB} \rightarrow p + \pi^0$, $p + \gamma_{CMB} \rightarrow n + \pi^+$, etc. Publicly available ones include:

- SimProp, SimProp-dev@aquila.infn.it
- CRPropa, http://crpropa.desy.de/

See R. Alves Batista, D. Boncioli, AdM, A. van Vliet and D. Walz, arXiv:1508.01824 for comparisons between them.

10/26

What we know and what we don't know

Things we know reasonably well:

- The expansion of the Universe (FLRW metric)
- The CMB spectrum and evolution (blackbody with $T = (1 + z)T_0$, $T_0 = (2.7255 \pm 0.0006)$ K)
- $p + \gamma \rightarrow p + e^+ + e^-$ cross sections (Bethe–Heitler formula)
- $\mathbf{p} + \gamma \rightarrow$ hadrons cross sections (lots of measurements)
- Total photodisintegration cross sections for certain nuclides

Things we know poorly or not at all:

- The EBL spectrum and evolution
- Photodisintegration branching ratios
- Details of hadronic interactions in the atmosphere

The extragalactic background light

- Hard to measure, due to large foreground (the zodiacal light)
- Can be estimated from:
 - observations of galaxy populations (e.g. Domínguez+ '11)
 - semi-analytical models of galaxy formation (e.g. Gilmore+ '12)

but results don't agree well, especially in the far IR and at high z

Photodisintegration cross sections: What we know

- Measurements of total cross sections available for many nuclides
- Phenomenological models in reasonable agreement with them; can be used to estimate cross sections for the other nuclides

Exclusive channel for one-neutron ejection also easily measured

Photodis. cross sections: What we don't know

- Exclusive channels for charged ejectiles hard to measure (ejectiles multiply scattered in the target)
- Measurements available for very few such channels; phenomenological models not always compatible with them

 α-particle ejection results in secondaries with 4× the energy of nucleon secondaries → different effect on UHECR spectrum

Boncioli, di Matteo, Grillo (INFN L'Aquila)

Surprises from UHECR propagation

Effect of different EBL models on propagated spectra

• Brighter EBL \rightarrow softer spectrum at Earth, lighter composition

See arXiv:1508.01824 for details

Introduction

- History of UHECR propagation studies
- Protons or nuclei?

Modelling issues

- Monte Carlo simulation codes
- Poorly known quantities (σ_{disi} and EBL) and their effects

3 Fitting source models to the data

4 Conclusions and future directions

Models and data

- Auger spectrum and X_{max} data fitted above $10^{18.7}$ eV (the ankle)
- Sources assumed to be identical, homogeneously distributed, injecting ¹H, ⁴He, ¹⁴N and ⁵⁶Fe with a power-law spectrum with rigidity-dependent broken exponential cutoff

$$\frac{\mathrm{d}N_{\mathrm{inj},i}}{\mathrm{d}E} = \begin{cases} J_0 p_i \left(\frac{E}{1 \text{ EeV}}\right)^{-\gamma}, & E/Z_i < R_{\mathrm{cut}} \\ J_0 p_i \left(\frac{E}{1 \text{ EeV}}\right)^{-\gamma} \exp\left(1 - \frac{E}{Z_i R_{\mathrm{cut}}}\right), & E/Z_i > R_{\mathrm{cut}} \end{cases}$$

- Various models for the propagation and air interactions used
- See AdM for the Auger Collab., PoS(ICRC2015)249 for details

Fit results

Models

- SimProp propagation
- PSB cross sections
- Gilmore+ '12 EBL
- EPOS-LHC air interactions

- $\gamma = 0.94^{+0.09}_{-0.10}$
- $R_{\rm cut} = 10^{18.67 \pm 0.03} \, {\rm V}$
- $0.0^{+29.9}\%$ H, $62.0^{+3.5}_{-22.2}\%$ He, $37.2^{+4.2}_{-12.6}\%$ N, $0.8^{+0.2}_{-0.3}\%$ Fe $D/n = 178.5/119 \ (p = 0.026)$

Fit results

Models

Introduction

- History of UHECR propagation studies
- Protons or nuclei?

Modelling issues

- Monte Carlo simulation codes
- Poorly known quantities (σ_{disi} and EBL) and their effects

3) Fitting source models to the data

4 Conclusions and future directions

Conclusions

- Propagation strongly sensitive to poorly known details of photodisintegration and EBL
 - This was unexpected until recently most analyses had only used one photodisintegration model and one EBL model at a time.
 - Improved photodisintegration or EBL measurements would be useful, but we aren't holding our breath.
- Auger data favour very hard, metal-rich injection spectra (especially for large σ_{α} and bright EBL), and dim EBL
- Data also compatible with no interactions
 - But local sources unlikely (limits on anisotropy)
 - On the other hand, no interactions predicted by some Lorentz-invariance-violating models, see Boncioli+ PoS(ICRC2015)521

Future directions

Things that still need to be done:

- What if we consider more than four possible elements at injection?
- What happens below the ankle?
 - An extra component would likely spill over above the ankle

Figure: 22% of flux at 10^{18.75} eV from dashed component in this model

• What about non-uniform source distributions?
