VERITAS and Cosmic Rays: An Update

Tuesday, September 15, 2015 9:00 AM (25 minutes)

VERITAS is a ground-based array of four 12-meter telescopes near Tucson, Arizona and is one of the world's most sensitive detectors of very high energy (VHE, $E > 100$ GeV) gamma rays. VERITAS has a broad scientific reach that addresses direct studies of cosmic-ray accelerators, the propagation of cosmic rays, and direct measurements of cosmic-ray spectra. Recent results include deep studies of the Galactic supernova remnants Tycho, Cassiopeia A, and IC 443, the search for gamma-ray emission associated with astrophysical neutrinos detected by IceCube, and a new measurement of the spectrum of cosmic-ray electrons. In this presentation, we will summarize the current status of the VERITAS observatory and present these and other recent results from VERITAS.
