# Introduction

Transitions are obtained by solving the pn-RQRPA equations

$$\begin{pmatrix} A & B \\ B^* & A^* \end{pmatrix} \begin{pmatrix} X^\lambda \\ Y^\lambda \end{pmatrix} = E_\lambda \begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix} \begin{pmatrix} X^\lambda \\ Y^\lambda \end{pmatrix}$$

Residual interaction is derived from the Lagrangian density

$$\mathcal{L}_{\rho+\pi} = -g_\rho \bar{\psi} \gamma_\mu \vec{\rho}^\mu \vec{\tau} \psi - \frac{f_\pi}{m_\pi} \bar{\psi} \gamma_5 \gamma^\mu \partial_\mu \vec{\pi} \vec{\tau} \psi$$

Total strength of a particular transition

$$B_{\lambda,J}(GT) = \left| \sum_{pn} \langle p \| \hat{O}_J \| n \rangle \left( X_{pn}^{\lambda,J} u_p v_n - Y_{pn}^{\lambda,J} v_p u_n \right) \right|^2$$

Decay rate:

$$\lambda_i = D \int_1^{W_{0,i}} W \sqrt{W^2 - 1} (W_{0,i} - W)^2 F(Z, W) C(W) dW$$

$$T_{1/2} = \frac{\ln 2}{\lambda}, \quad D = \frac{(G_F V_{ud})^2 (m_e c^2)^5}{2\pi^3 \hbar}$$

Allowed decays shape factor:

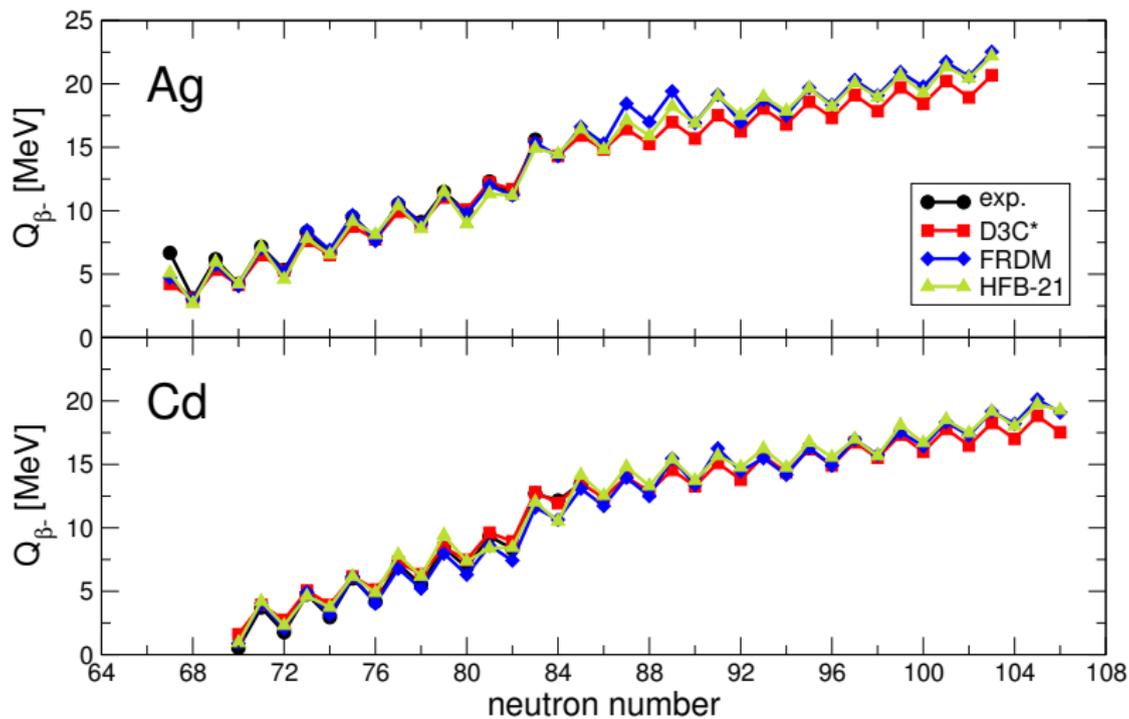

$$C(W) = B(GT)$$

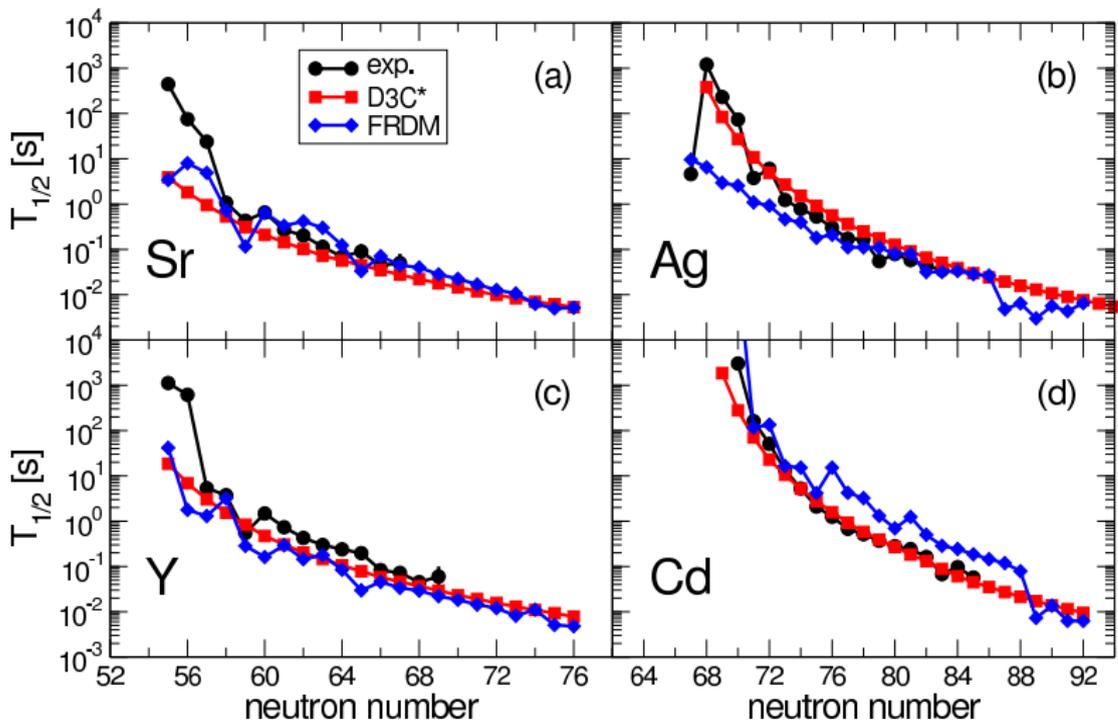

First-forbidden decays shape factor:

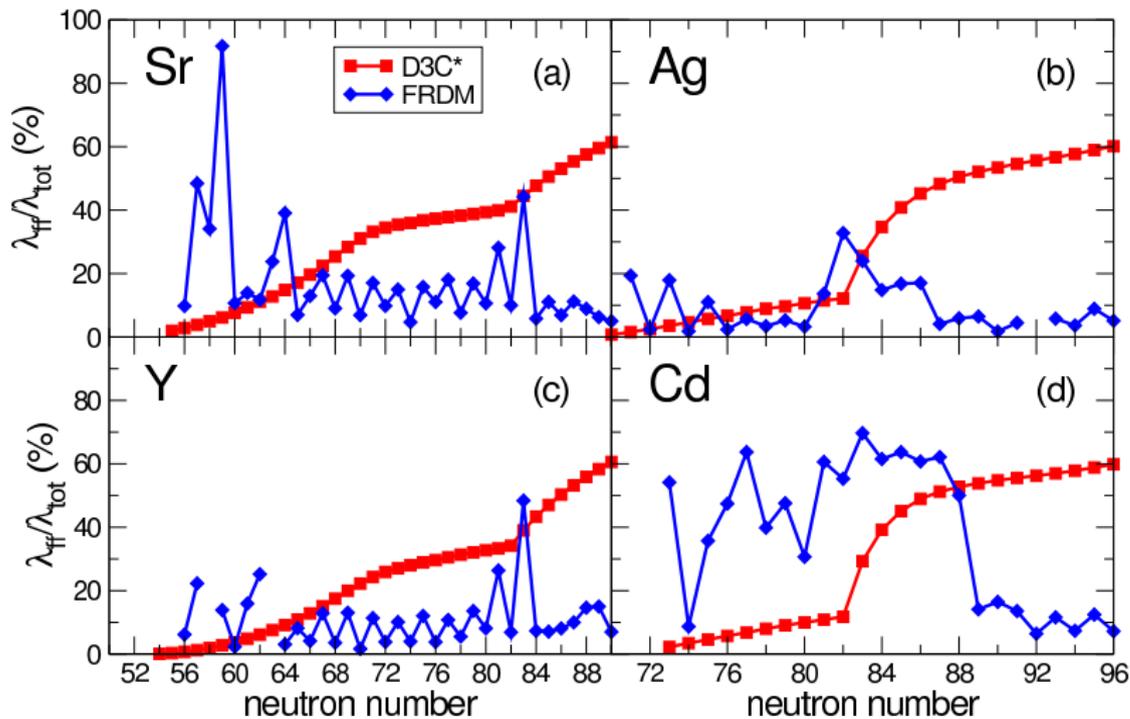

$$C(W) = k \left( 1 + aW + bW^{-1} + cW^2 \right)$$

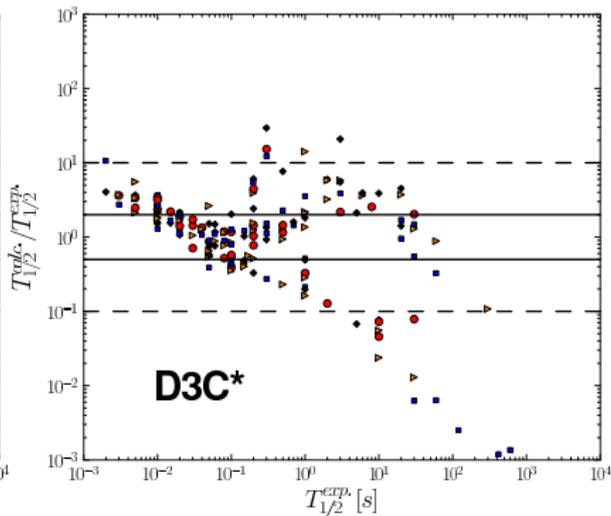

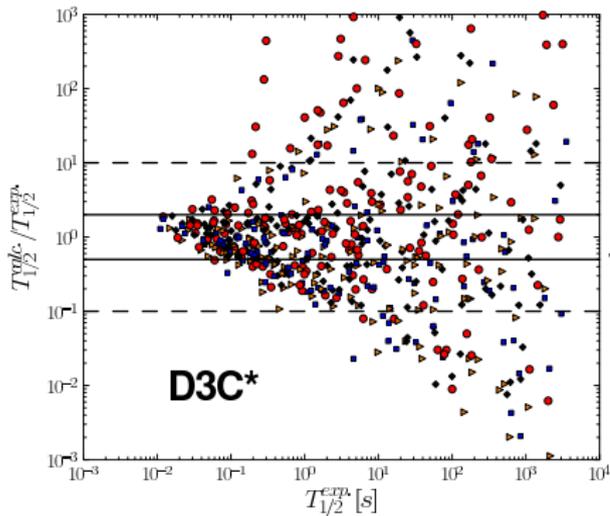

$$\begin{aligned}

$$\langle n \rangle = \sum_i iP_{in}$$

# Evaluation of reactor antineutrino spectra

In reactors, 99% of the electrons come from decay of fission products of 4 nuclei.

$$S_{tot}(E) = \sum_{k=^{235}\text{U}, ^{238}\text{U}, ^{239}\text{Pu}, ^{241}\text{Pu}} \alpha_k S_k(E),$$

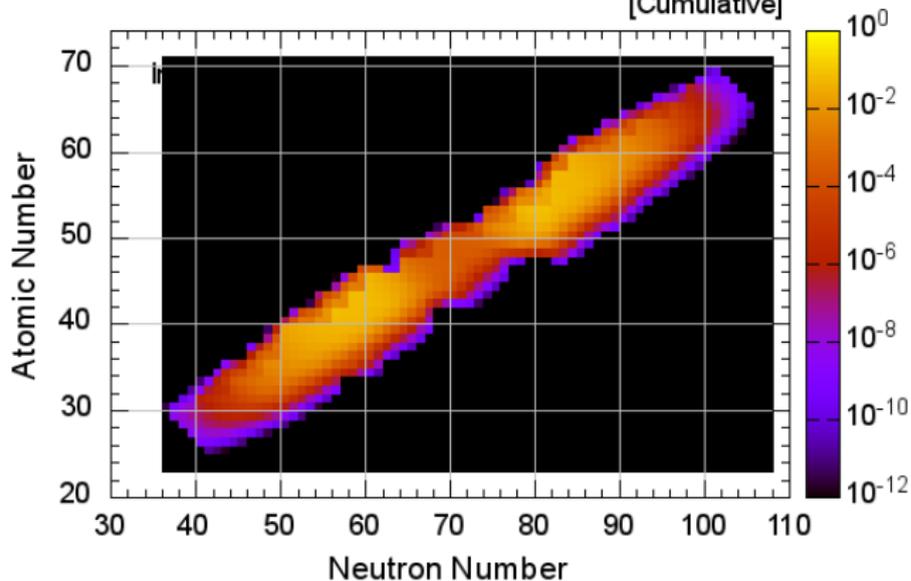

- $\alpha_k$  - number of fissions at considered time
- $S_k(E)$  -  $\beta$  spectrum normalized to one fission
- $E$  - kinetic energy of emitted electrons

Electrons (and antineutrinos) come from the  $\beta$ -decay of resulting fission fragments.

$$S_k(E) = \sum_{f=1}^{N_f} Y_f S_f(E)$$

$$S_f(E) = \sum_{i=1}^{N_t} \frac{\lambda_i}{\lambda_{tot}} S_f^i(Z, A, E_{max}, E).$$

JAEA Nuclear Data Center

For allowed transitions the spectrum reads

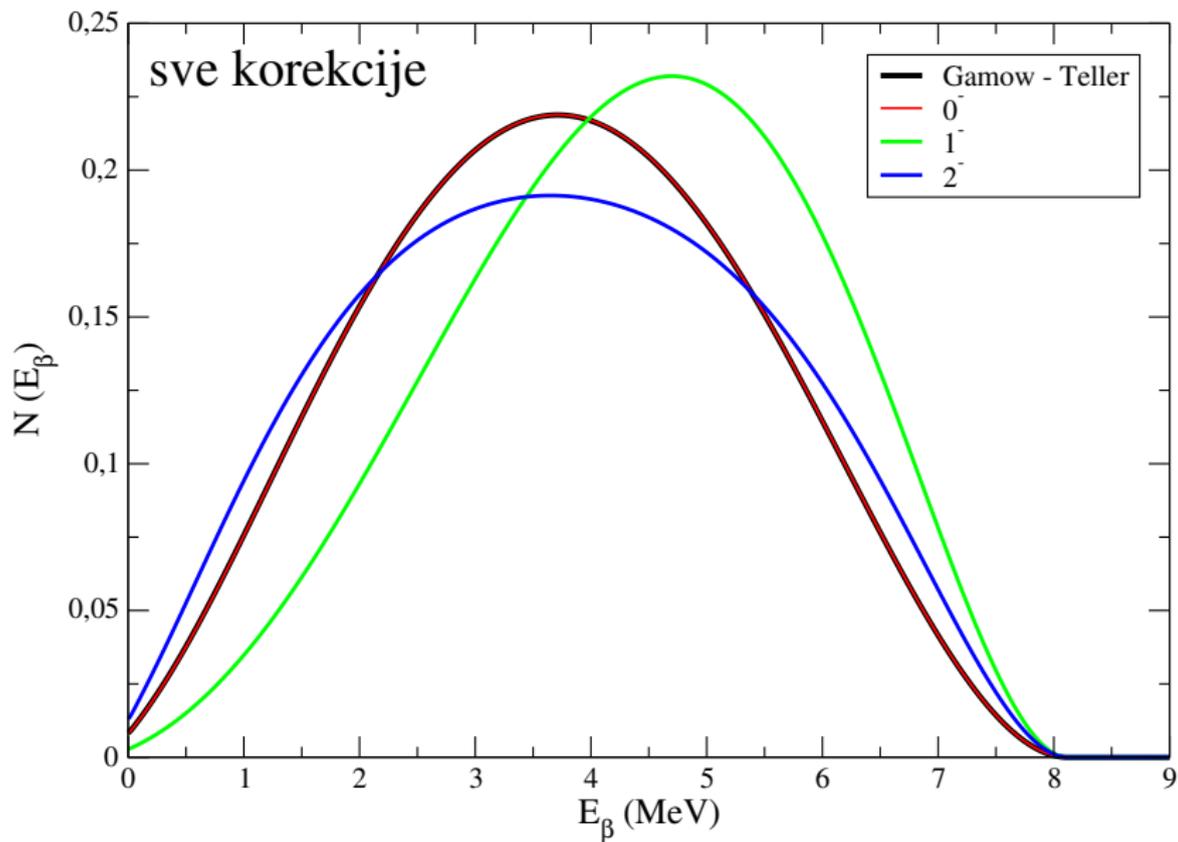

$$S_f^i = F(Z, A, E) \cdot pE(E - E_{max})^2 \cdot L_0(Z, E) \cdot C'(Z, E)$$

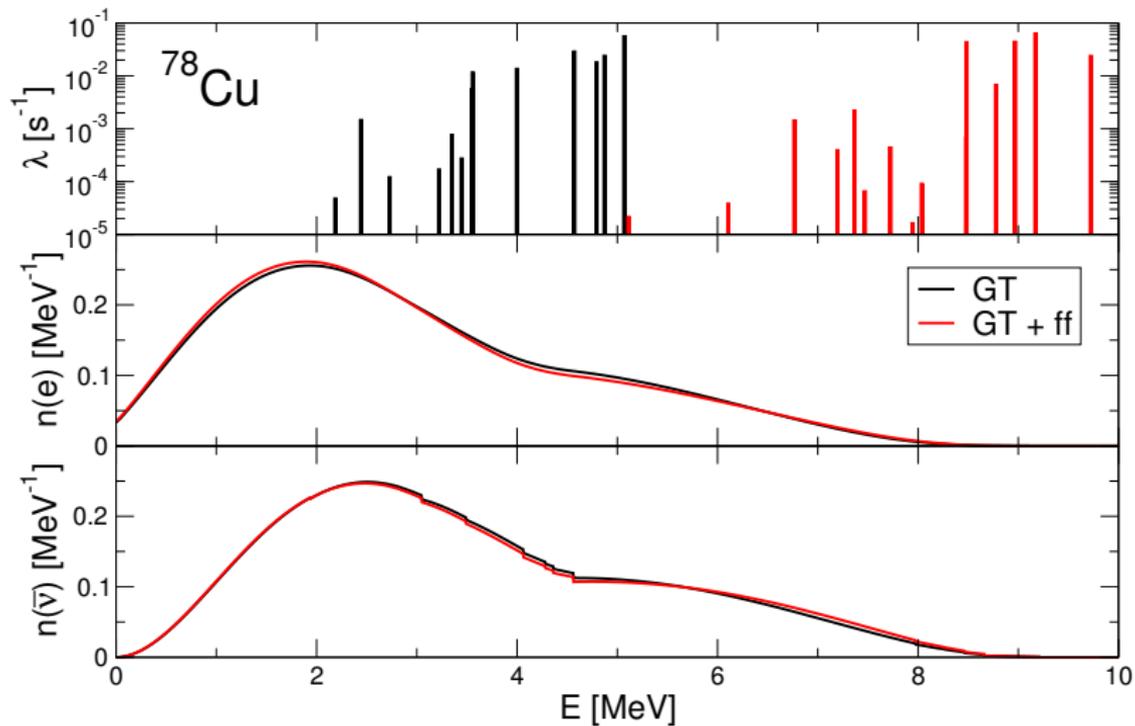

- $F(Z, A, E)$  - Fermi function, correction for the Coulomb field
- $L_0(Z, E)$  - correction for the finite size of the charge distribution
- $C'(Z, E)$  - correction for the nucleon moving within a nuclear potential
- other corrections are neglected

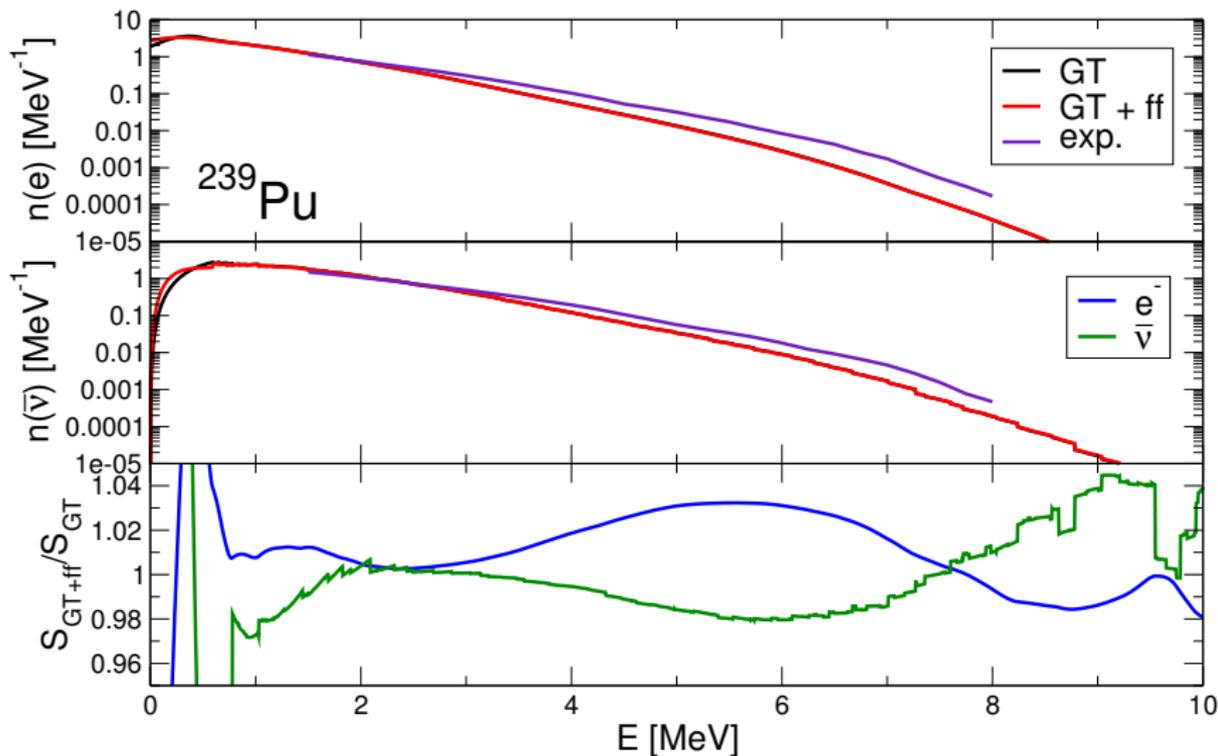

but if we include first-forbidden transitions

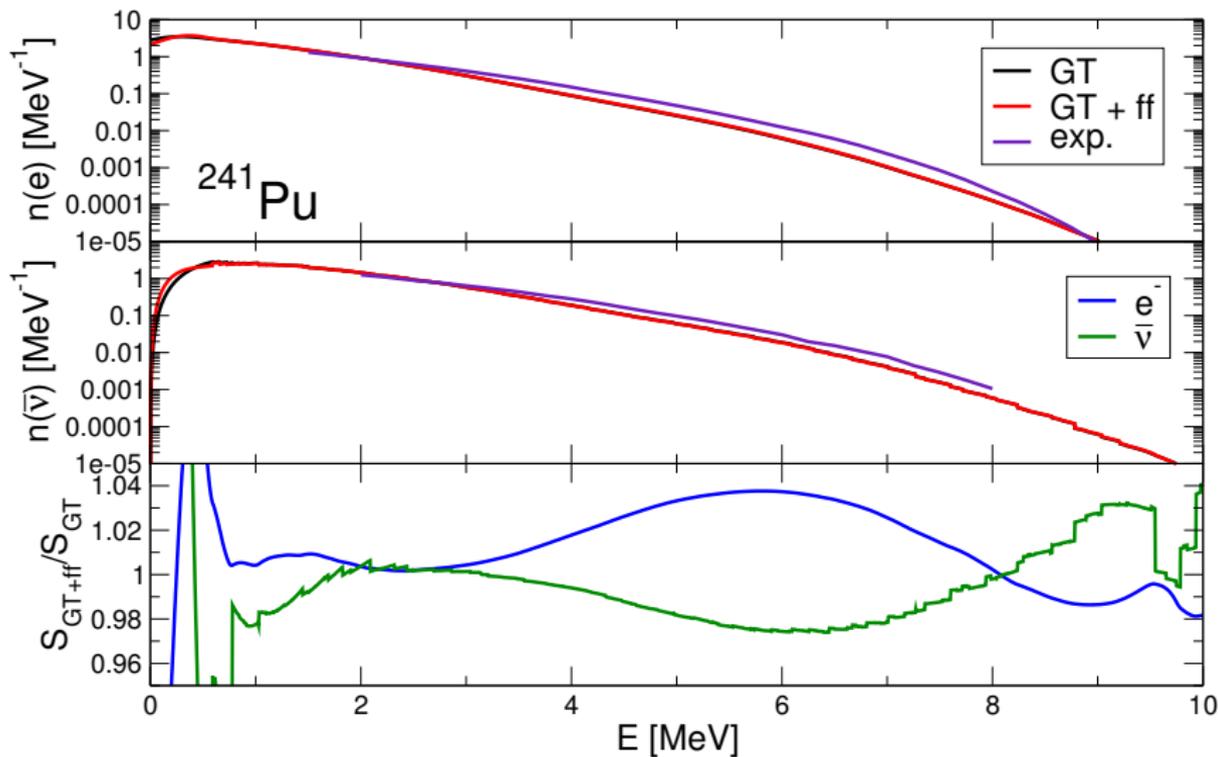

$$S_f^i = F(Z, A, E) \cdot pE(E - E_{max})^2 \cdot C(E) \cdot L_0(Z, E) \cdot C(Z, E)$$

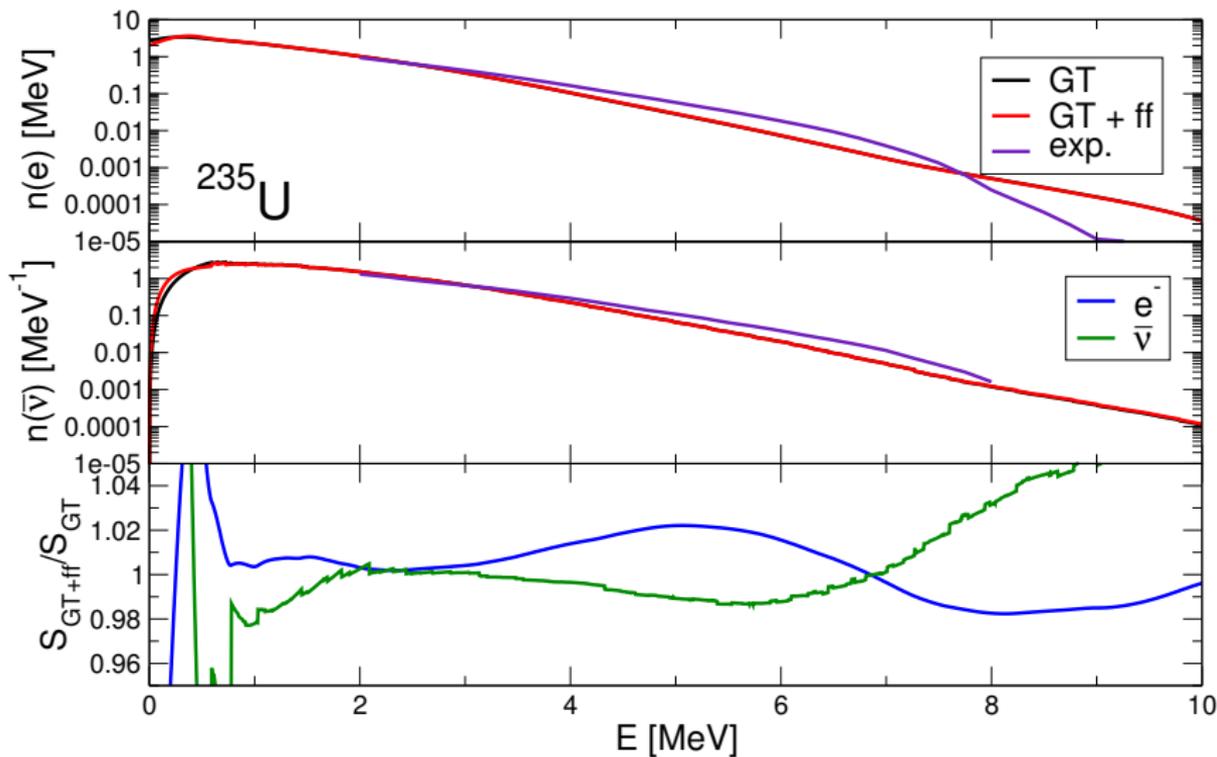

where  $C(E)$  is the *shape factor*
