# NEutron and Proton IRradiation Facility at SPES

NEPIR

*A SPES delta-phase project involving:*

NEUTARGS Padova collaboration

INFN / Padova: D. Bisello, L. Silvestrin, J. Wyss

INFN / LNL: J. Esposito, A. Lombardi, M. Maggiore, P. Mastinu,  
G. Prete, D. Zafiropoulos, L. Sarchiapone

INFN / Milano: G. Gorini

CNR: C. Andreani

*Project coordinator*

“Core business”: radiation damage effects in electronics

- **Atmospheric neutrons** (avionics and ground-based electronics)
- **Solar protons** (space applications)

**Versatile**  $\Rightarrow$  other applications too

# Neutrons are a widening problem for Industry

Aviation

Automotive

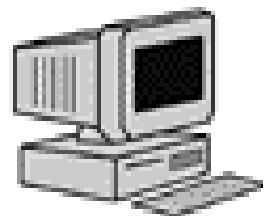

Trains

Infrastructure  
and InfoTech

**“Radiation induced single events could be happening on everyone’s PC, but instead everybody curses Microsoft.”**

*Paul Dodd, Sandia National Laboratories*

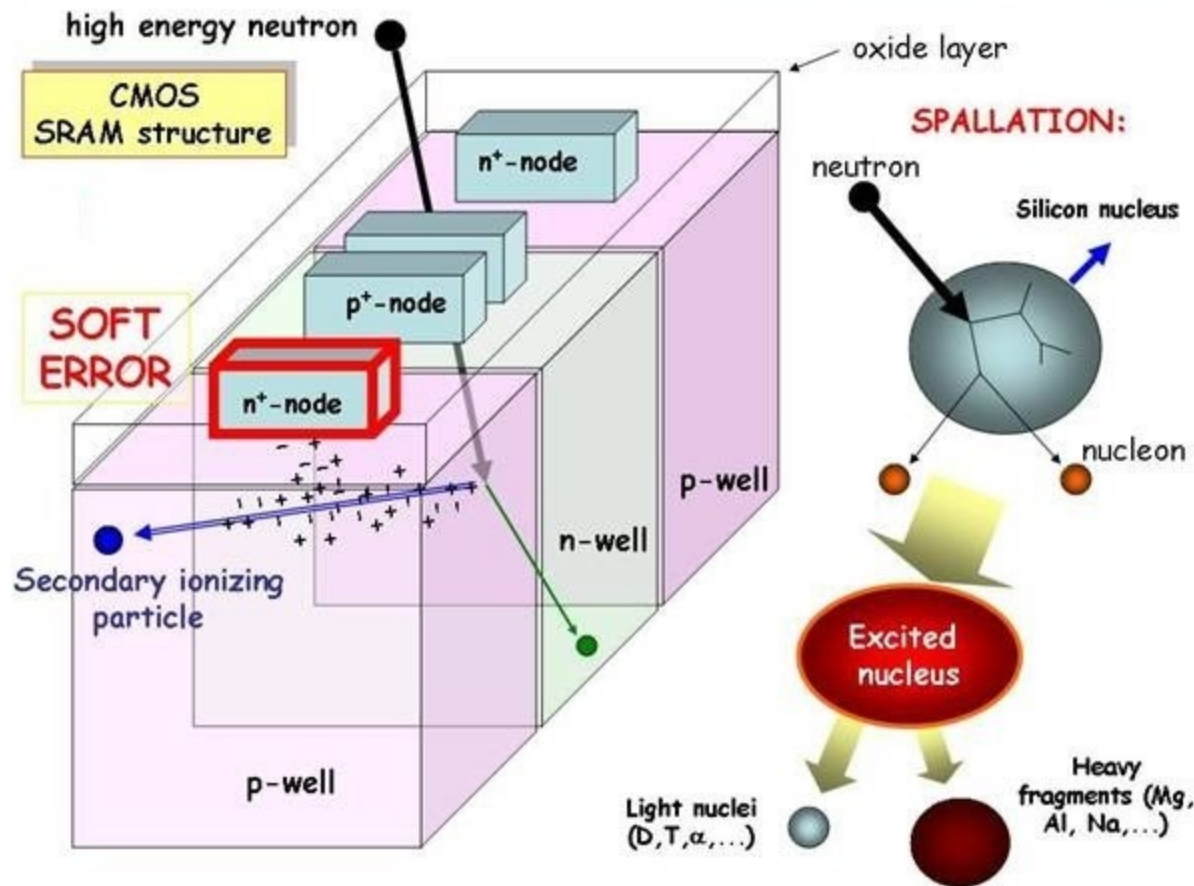

Medical

# Physics of neutron-induced SEE

(1) Primary neutron  
(accelerator, cosmic-rays,...)

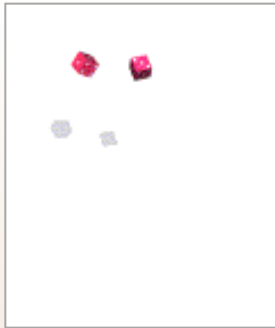

(2) neutron-nucleus reactions with  
production of ionizing secondaries  
(Nuclear Physics)

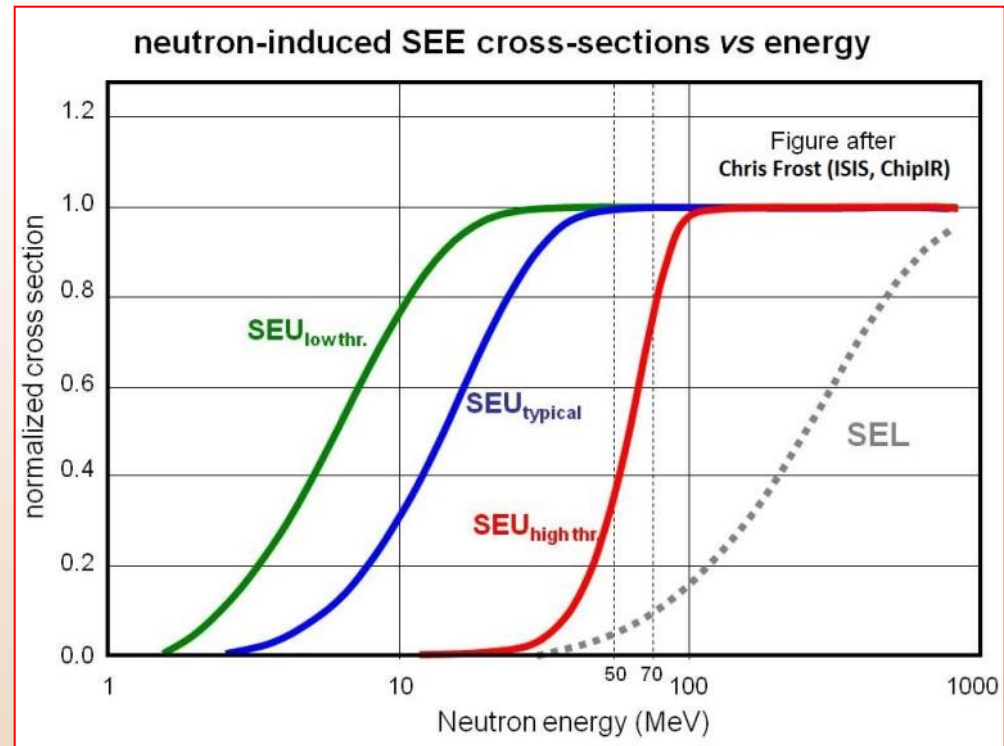

(4) Charge transport in device  
(device physics)

(3) Generation of electron-hole pairs  
(radiation physics and solid-state physics)

# If neutron is fast enough a SEE may occur

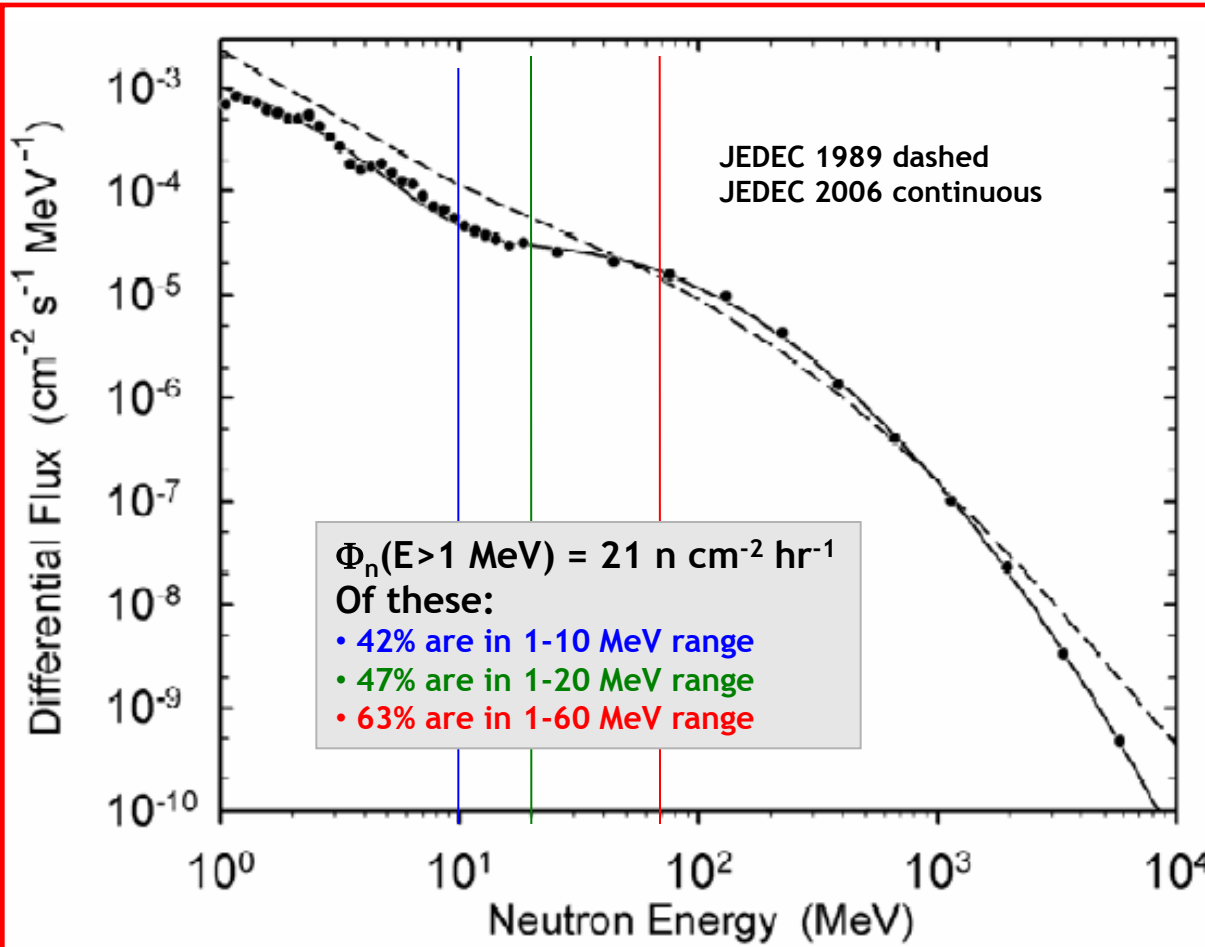

Typically, neutron-induced SEE occur when the energy of the impinging neutron is above some minimum **threshold value**; the probability of a SEE occurring, usually expressed as a **cross-section**, **increases with neutron energy**, until a **plateau value** is reached.

Weibull fit function for a typical cross section curve

$$\sigma(E) = \sigma_P \left( 1 - e^{-\left[ \frac{E - E_{thres}}{W} \right]^S} \right)$$

# Spectrum $\phi_{atm}(E)$ of fast ( $E > 1 \text{ MeV}$ ) atmospheric neutrons

JEDEC 2006 reference curve is fit to data (Gordon)

- sea level
- New York City
- mid-level Solar activity
- outdoors

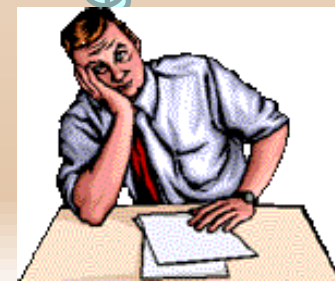

Typical value for SEU

$$\sigma_{\text{Plateau}} = 10^{-14} \text{ cm}^2/\text{bit}$$

gives

$$4 \text{ SEU} / (\text{month} \cdot 8 \text{ GByte})$$

(yawn)  
I need to speed things up...  
I want an accelerator!

And the rate of neutron-induced Single Event Upsets (SEU) in a device located at New York City (NYC) is...

$$R_{SEU}^{NYC} = \int_{E_{th}}^{\infty} \sigma_{device}(E) \phi_{atm}(E) dE = N_{bits} \times \int_{E_{th}}^{\infty} \sigma_{bit}(E) \phi_{atm}(E) dE$$

# Neutron SEE tests: **field** and **accelerated**

Type	Experimental Method	Merit/demerit
Neutron Field Tests	Keep a large number of device under test (DUT) at a certain location for a long time.	<ul style="list-style-type: none"> <li>• costly, time consuming</li> <li>• realistic and reliable</li> <li>• few corrections necessary (related to altitude and location)</li> </ul>
<b>Monoenergetic Neutrons</b> <i>Thin light targets</i>	Irradiate DUT with mono-energetic neutrons. Vary energy of the neutrons to study energy dependent effects	<ul style="list-style-type: none"> <li>• facilities limited</li> <li>• versatile</li> <li>• actually neutrons are quasi-mono-energetic (QMN), hence corrections are necessary to account for significant fraction of neutrons with wrong energy.</li> </ul>
<b>Evaporation and Spallation Neutrons</b> <i>Thick targets</i>	Irradiate DUT with neutrons of a broad energy range similar to atmospheric neutron spectrum.	<ul style="list-style-type: none"> <li>• high fluxes</li> <li>• facilities limited</li> <li>• continuous (white) spectrum needs to be similar to atmospheric one</li> <li>• uncertain in selection of energy range</li> </ul>
<b>Thermal Neutrons</b>	Irradiate DUT with thermal neutrons at experimental reactors or using targets with moderators	<ul style="list-style-type: none"> <li>• facilities limited</li> <li>• using reactors the estimation of SEE rate in field is difficult due to great difference in neutron spectra</li> </ul>
<i>Proxy mono-energetic protons</i>	<i>Irradiate DUT with mono-energetic protons. Vary the energy of the protons to study energy dependent effects.</i>	<ul style="list-style-type: none"> <li>• many facilities available</li> <li>• pseudo-equality with neutron nuclear cross-sections</li> <li>• ionization dose effects in DUT</li> </ul>

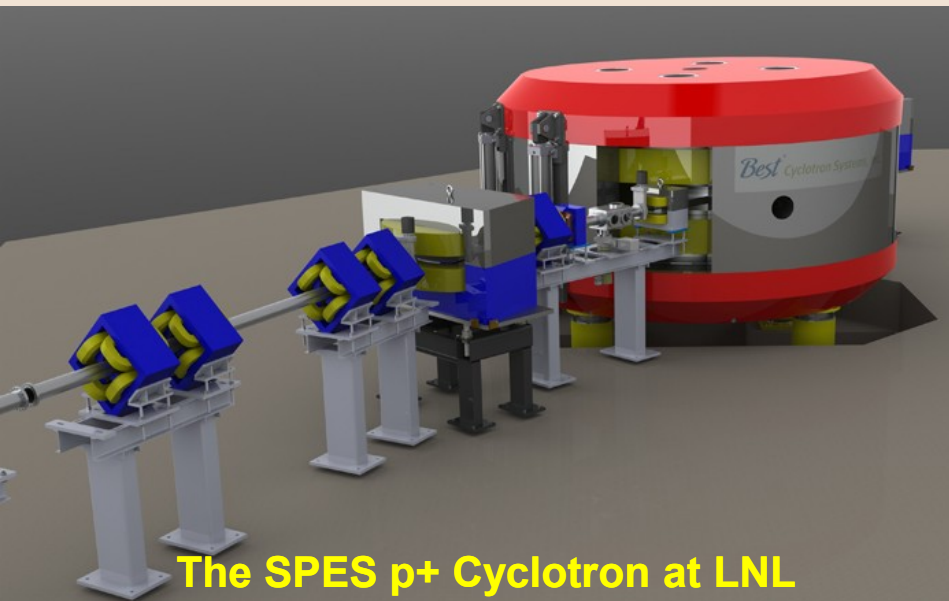

# Accelerated SEE studies and tests

Useful probes:

- (quasi) Mono-energetic neutrons  
to study energy dependence effects
- Continuous energy neutrons  
to emulate atmospheric neutrons

$$R_{SEE}^{test} = F \times \int_{E_{th}}^{cutoff} \sigma_{device}(E) \varphi_{atm}(E) dE$$

F is the “acceleration factor”

The SPES p+ Cyclotron at LNL

At the INFN National Labs of Legnaro (LNL), a variable energy (35-70 MeV) high current proton cyclotron ( $I_{\max} = 750 \mu\text{A}$ ) will soon come into operation.

It will open up the **prospect of high flux neutron facilities in Italy** that could perform various research activities.

# Tools at the proposed neutron facility (NEPIR)

## Fast Quasi Mono-energetic Neutrons (QMN) from 35-70 MeV protons

- multi-angle collimator for “tail correction”
- assortment of thin (2-4 mm) Li and Be targets

## Continuous energy (*white*) atmospheric-like neutrons from intense 70 MeV protons

### Two high power targets:

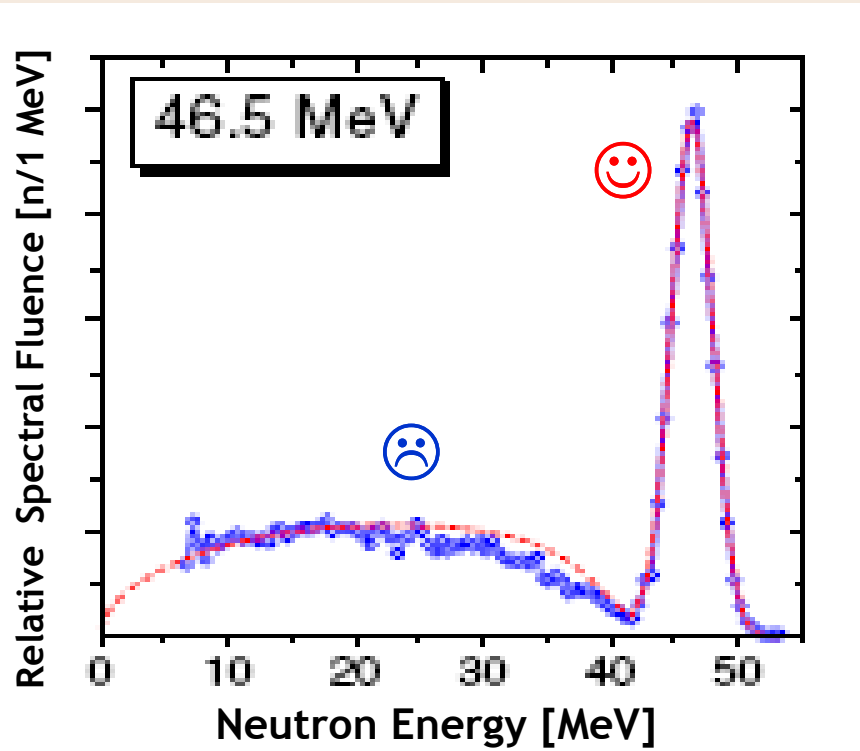

- a) Slow neutrons: a “conventional” *thick (stopping)* W-based target and moderator system (49 kW) (SLOWNE)
- b) Fast neutrons: a “novel” rotating BePb (or BeTa) composite target system, *relatively thick* (non-stopping), without moderator (ANEM)

## *Direct protons (35-70 MeV, low current)*

# 1) Monoenergetic Neutrons ... almost (QMN)

Well defined energy neutrons are produced in  ${}^7\text{Li}(p,n)$  and  ${}^9\text{Be}(p,n)$  reactions. However the experimental neutron spectrum is not purely mono-energetic because neutrons released during nuclear break-up can assume a continuous range of energy values.

In the **forward direction** ( $\theta = 0^\circ$ ) only about half of the neutrons form a peak with a well defined energy (😊), while the rest have lower energies distributed over a broad range of values (😞).

Typical **forward** QMN spectrum at **Zvedberg (TSL)** for  $E_{\text{proton}} = 49.5 \pm 0.2 \text{ MeV}$  on **thin (4 mm) Lithium slab**.

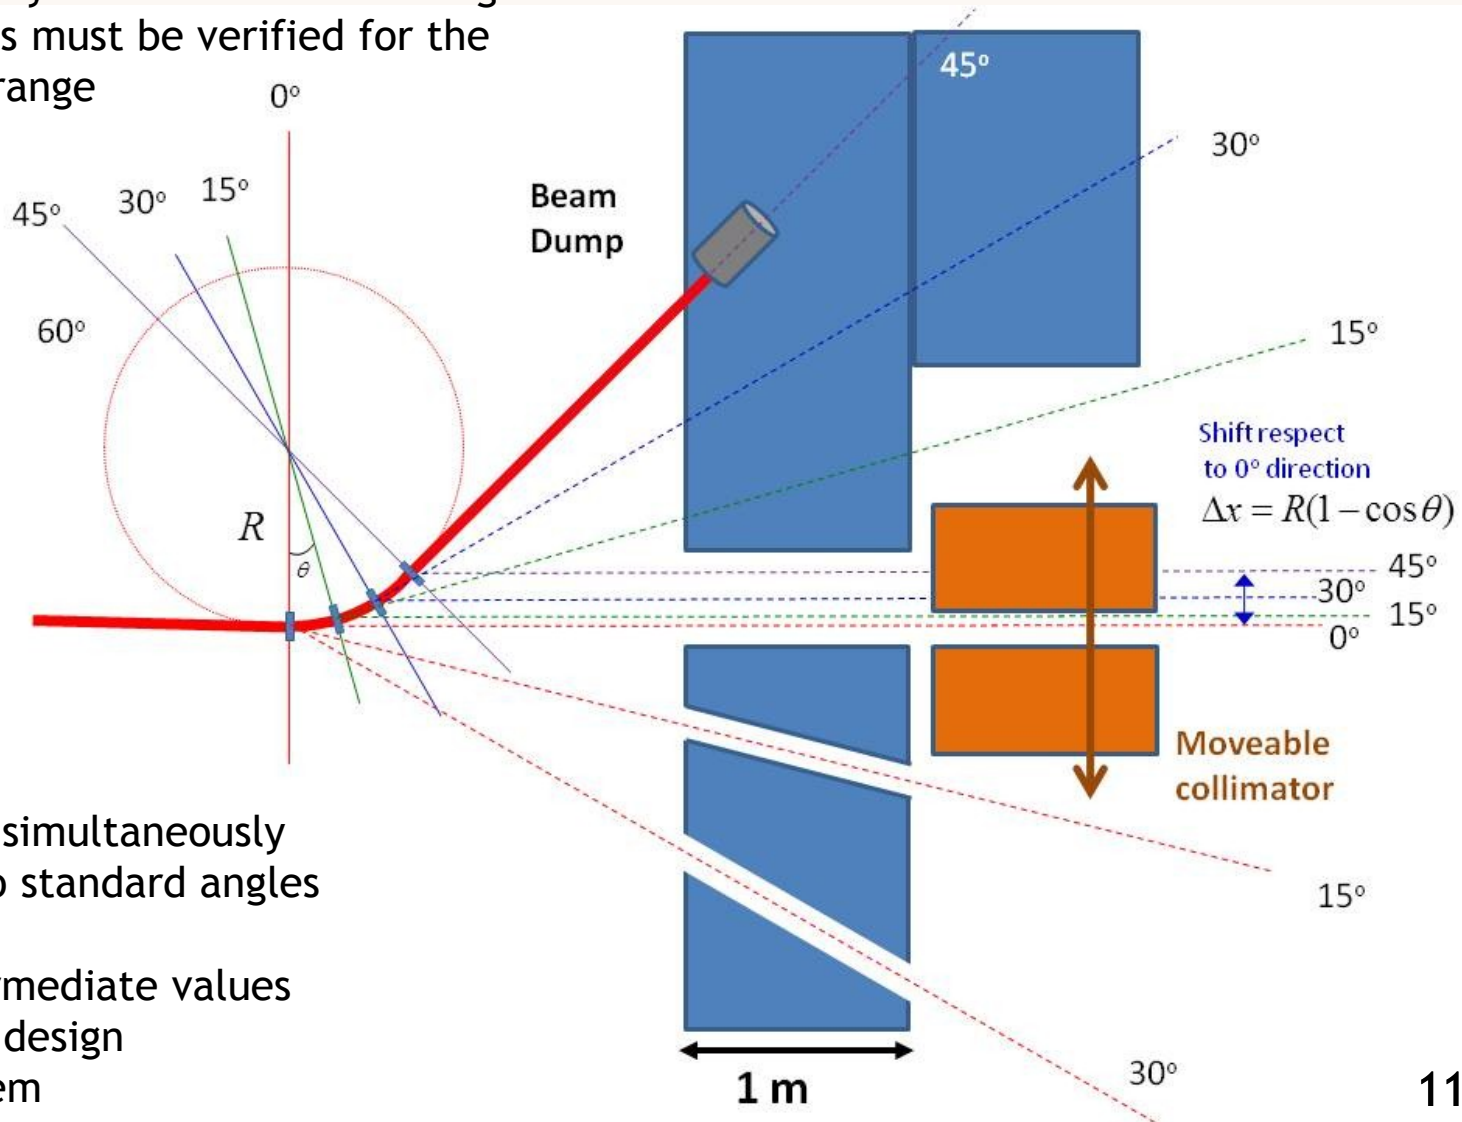

- Thin  $\Rightarrow$  must pay price of lowered neutron yield/current
- The protons that do not undergo nuclear reactions ( $\sim 99\%$ ) are magnetically deflected towards a beam dump.

## QMN tail subtraction

PERFORMANCE for 1mm and 2mm Be slabs: n flux at test point  $> 3 \times 10^5 \text{ n cm}^{-2} \text{ s}^{-1}$

Limited neutron yield => high current:  $50\mu A$  max

A 30° collimator is likely to be the standard angle for correction, but this must be verified for the 20-35-70 MeV energy range 0°

- data can be taken simultaneously at  $0^\circ$  and one or two standard angles (say  $15^\circ$  and  $30^\circ$ )
- flexibility for intermediate values
- but challenging to design magnet/target system

# Forecast of EURADOS report

EURADOS Report 2013-02

Braunschweig, May 2013

The Report concludes that, out of the worldwide six QMN facilities currently in existence, all operate in sub-optimal conditions for dosimetry. Of the three facilities in Japan, one is at least temporarily out of action, and the only currently available QMN facility in Europe capable of operating at energies above 40 MeV, TSL in Uppsala Sweden, is threatened with shutdown in the immediate future. In Europe, a facility, NFS at GANIL, France, is currently under construction. NFS could deliver QMN beams up to about 30 MeV. It is, however, so far not clear if and when NFS will be able to offer QMN beams or operate with only so-called white neutron beams. It is likely that in about five years, QMN beams with energies above 40 MeV will be available only in South Africa and Japan, with none in Europe.

The QMN beam line of NEPIR would close the gap. It is of the highest priority, as it would be a precious multidisciplinary tool making NEPIR an important reference point for Italian and European research, applied and basic.

The risk of shut-down of the TSL radiation damage facilities is because the accelerator beam is increasingly used for proton therapy.

# SLOWNE: a conventional continuum spectrum target

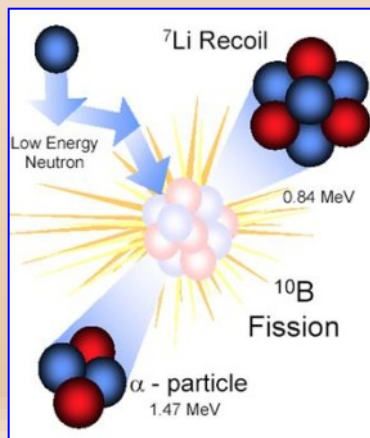

It is *conventional* in that

1. it produces the largest amount of neutrons possible...
2. ...and then the neutron spectra is *shaped* using moderators

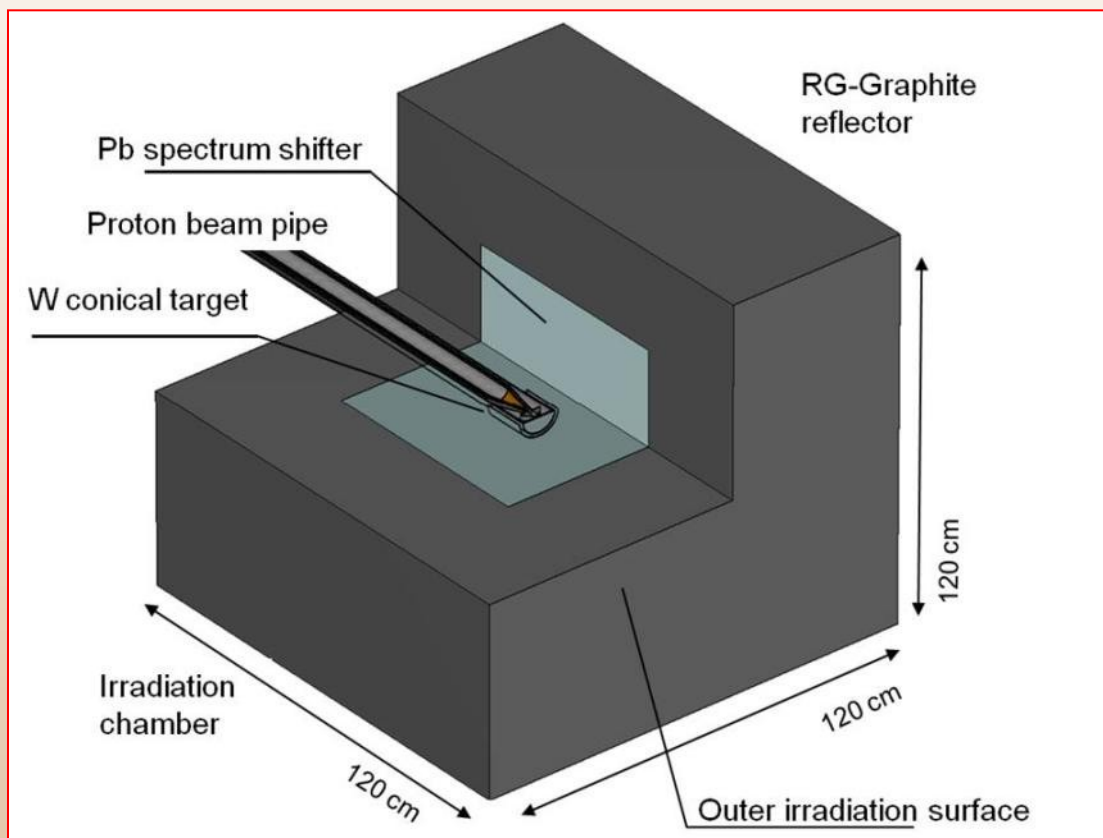

The target for the high neutron flux beam line is a **thick** W-based self-shielding production target that **completely stops the proton beam**.

Moderators and reflectors are then used to **SLOW** the neutrons and shape the energy spectrum to resemble the desired one, namely the atmospheric spectrum

also down to epithermal and thermal energies.  
Thermal neutrons may cause SEE if  $^{10}\text{B}$  is present in device under test (same used for BNCT).

Thick target W-based target (FARETRA\*-like)

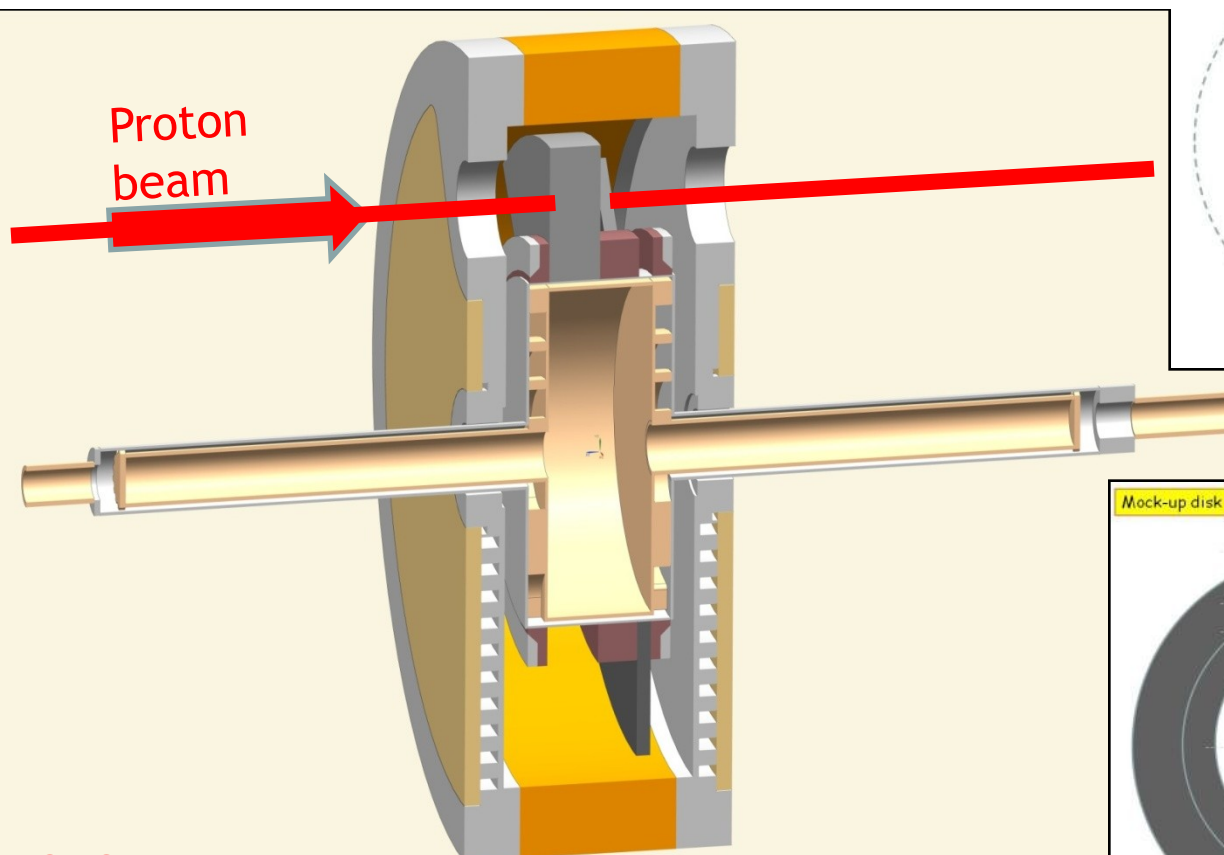

\* FARETRA = Fast REactor simulator for TRANsmutation studies

# Atmospheric-Neutron Emulator (ANEM) for SEE studies

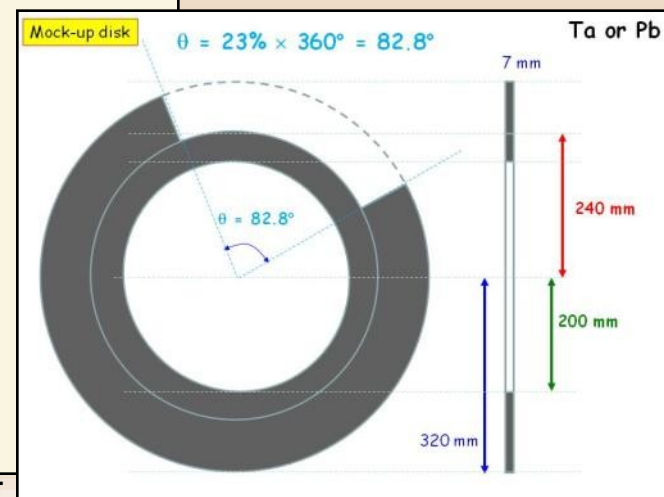

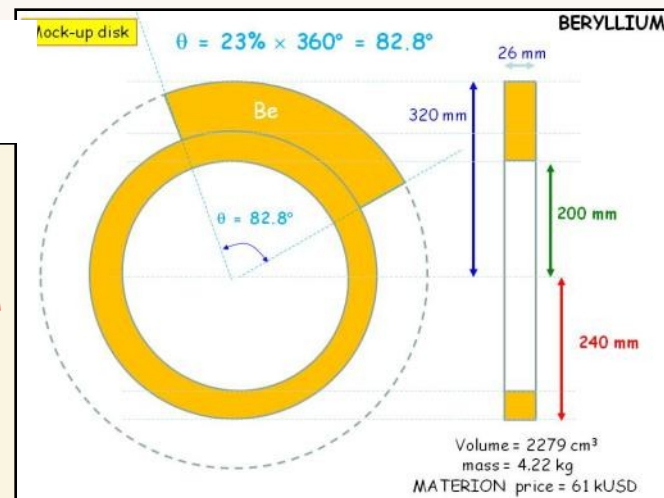

**Composite Be-Pb system:** Two complementary disks, rotating on a common hub, alternatively intercept the off axis proton beam; the beam is **NOT stopped by Be** (to avoid damaging due to blistering), the spent protons are the magnetically deflected towards a beam dump (shared with QMN).

The LENOS chamber with modified innards to **house Be and Pb (or Ta) "disks" and water flow system.**

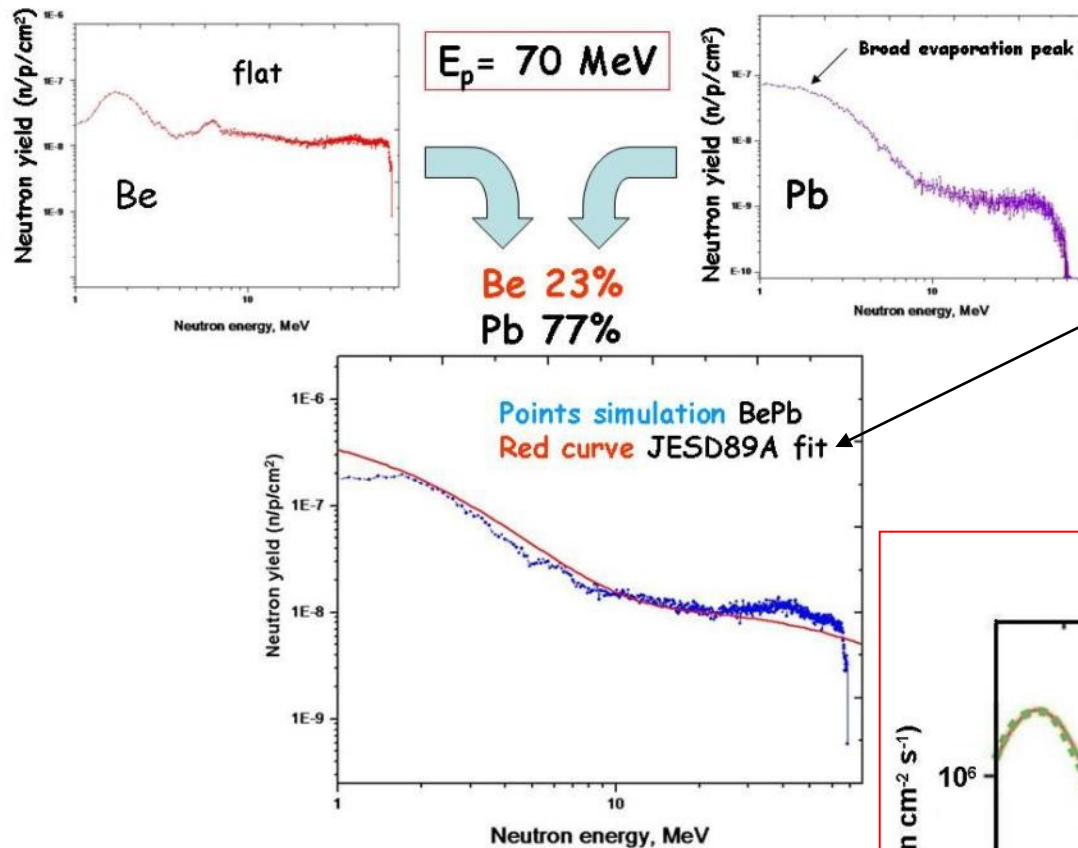

**ANSYS simulations under way.**

**Thermal tests with Al disk foreseen in the next months.**

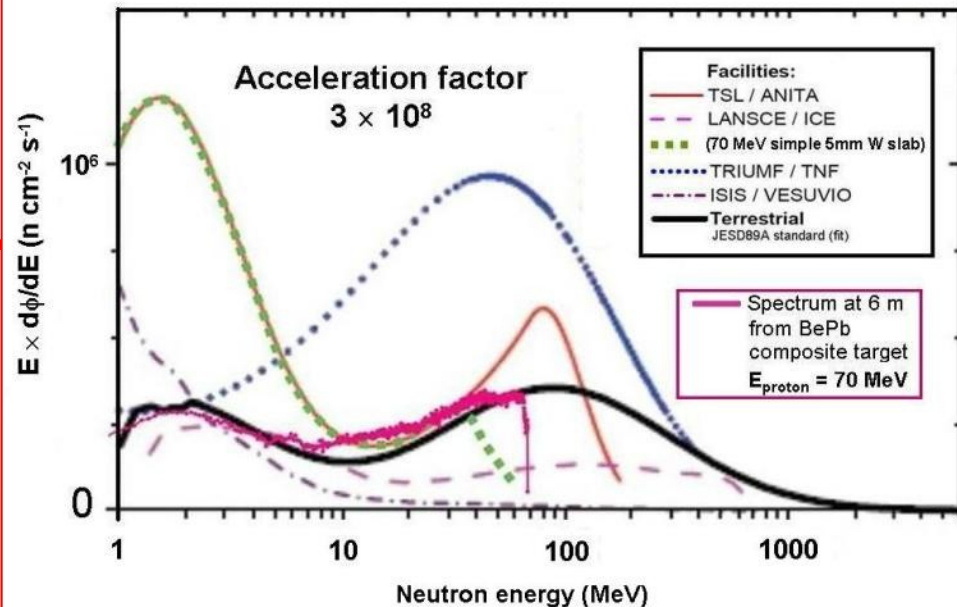

# Fast neutron energy spectrum of ANEM (BePb variant)

**Atmospheric neutrons at sea level at New York**  
 integrated flux  $E > 1 \text{ MeV}$   
 $\phi_n (E > 1 \text{ MeV}) = 21 \text{ cm}^{-2} \text{ hr}^{-1}$

*Lethargy representation*

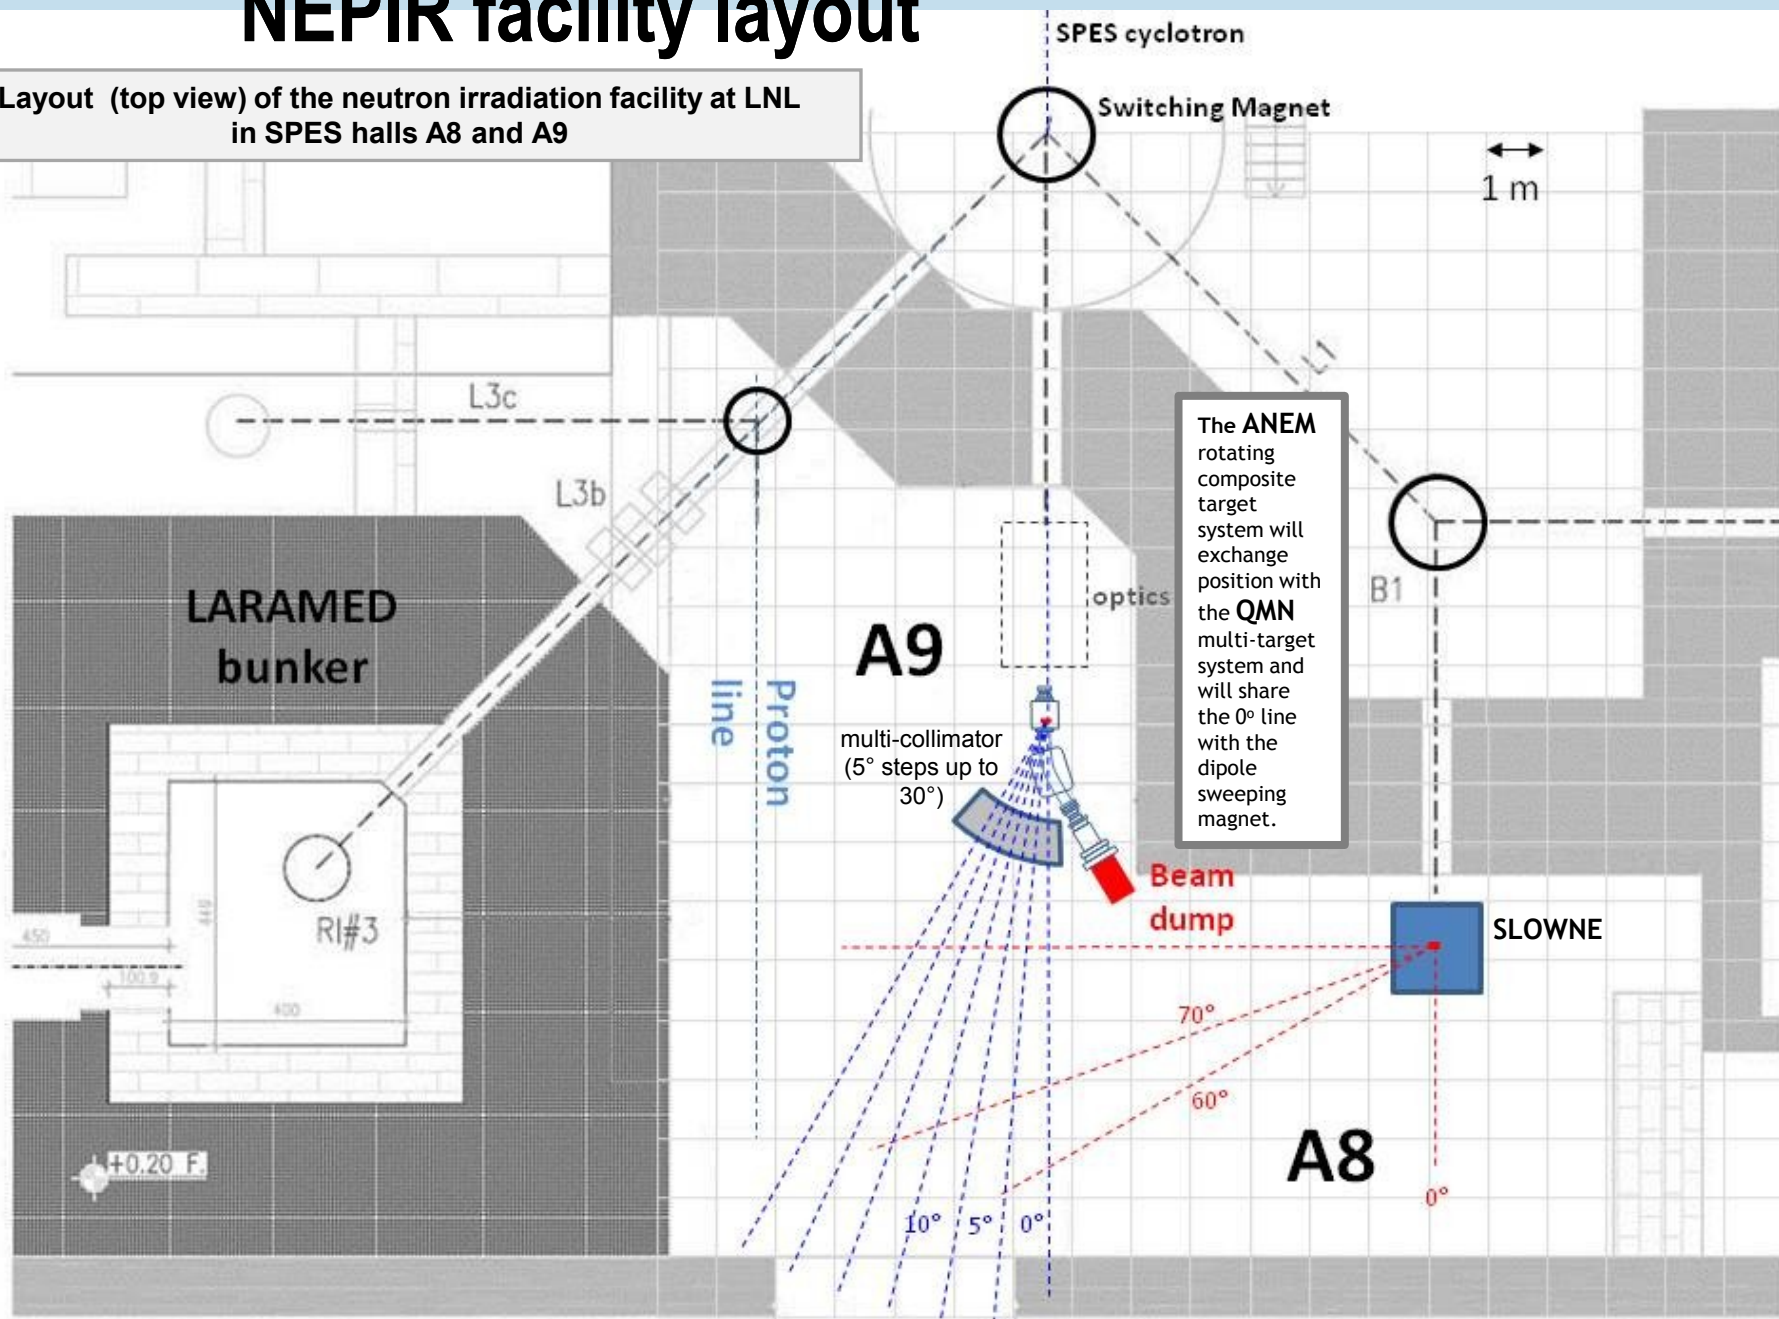

**Neutron FLUX** at 6 m from the target:  $20\text{-}30 \times 10^9 \text{ n cm}^{-2} \text{ s}^{-1}$   
 (current:  $50\text{-}100 \mu\text{A}$ )

An "acceleration factors" of few  $10^9$  can be achieved with few tens of  $\mu\text{A}$ .

# NEPIR facility layout

Layout (top view) of the neutron irradiation facility at LNL in SPES halls A8 and A9

**SPES hall A9, side view**

### Chicane to:

- avoid neutrons towards cyclotron
- have test point at same distance from floor and ceiling (minimize albedo)
- use degrader for lower energy neutrons

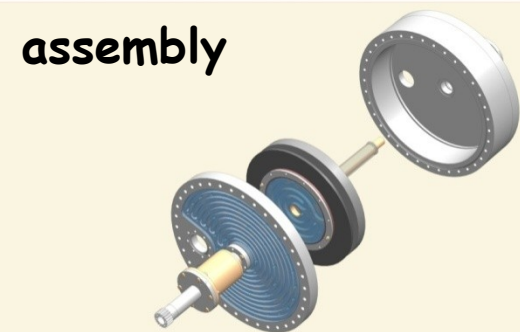

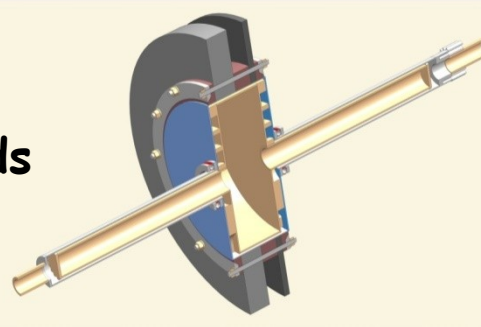

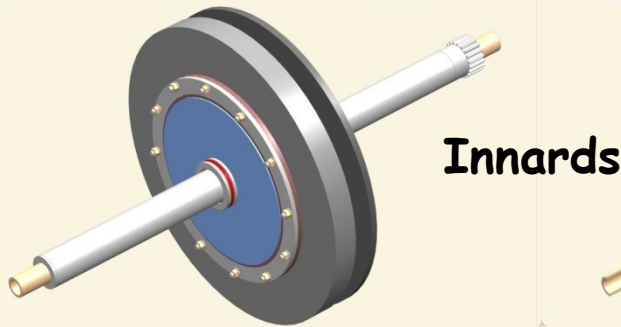

- The rotating composite BePb target system will exchange position with the QMN multi-target system and will share the 0° line with the dipole sweeping magnet.

with the QMN multi-target system and will share the 0° line with the dipole sweeping magnet.

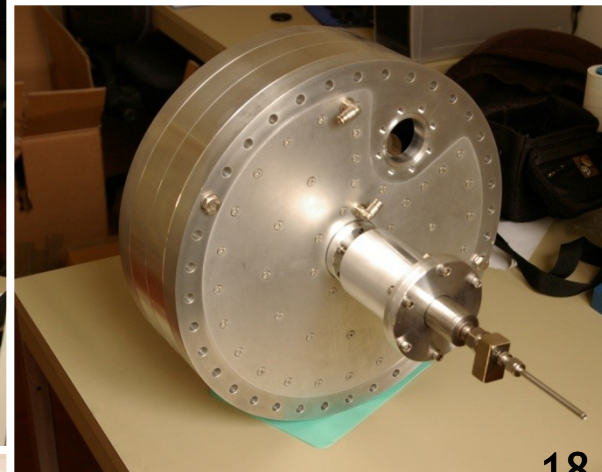

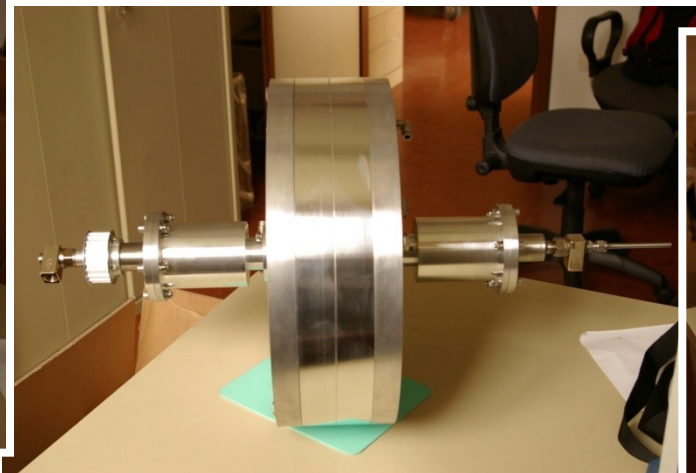

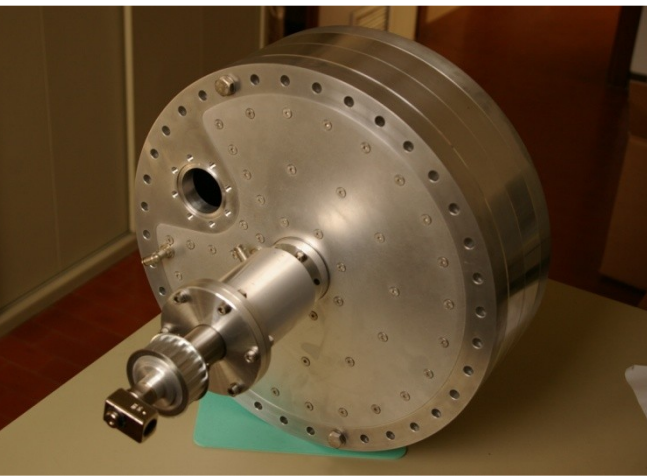

**At the test point, the neutron beam is 1.50 m from the false floor (3.91 m from the bottom cement floor). The optics consists of two dipole magnets, two quadrupole doublets and a single one, and a bending magnet for the spent proton beam. The supplementary shielding is not shown.**

# The ANEM prototype (mock-up) system

A mock up of the target was manufactured to perform the measurements of power dissipation necessary to tune the ANSYS simulations, to test the rotation system and tune the cooling system.

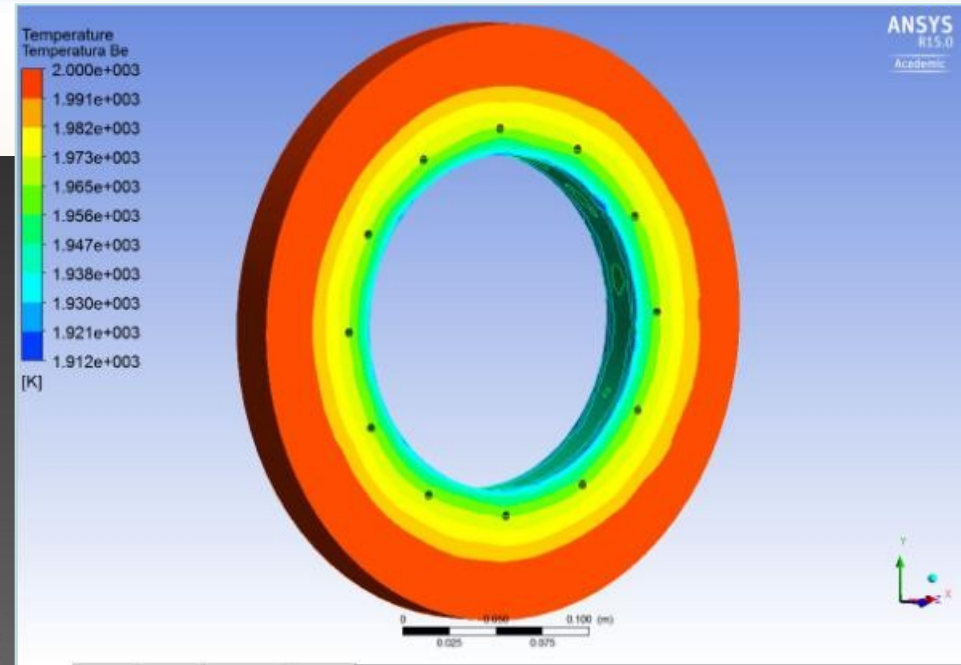

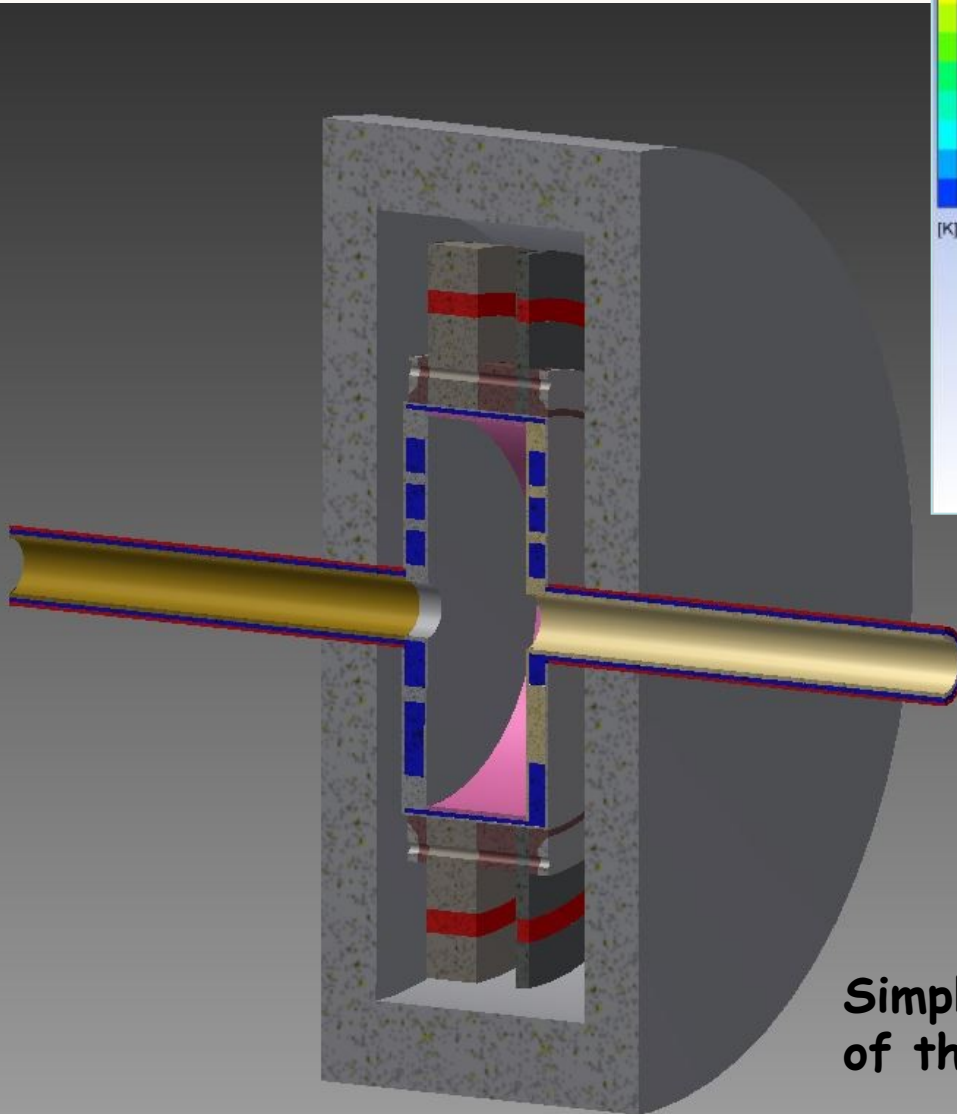

The mock up employs the existing vacuum chamber of the Lenos project while new innards were manufactured. The element exposed to the beam is a 7mm thick Al (99%) ring.

# What's next

MCNPX/Fluka simulations to assess target shielding and collimator system are ongoing. The design of beam dump will limit the maximum neutron flux.

To experimentally define key heat transfer parameters, thermal tests will be performed with the mock up target in the next months, using a high power electron gun.

New ANSYS simulations will be performed using the experimentally defined parameters. These will be used to **validate the final design** of the target, or to suggest modifications.

# NEPIR

Particle and spectrum	Energy	Max flux at test point (SPES current)
neutron (discrete)	Adjustable QMN peak in 35-70 MeV energy range	Few $10^6$ n cm <sup>-2</sup> s <sup>-1</sup> ( 50 $\mu$ A max)
neutron (continuous)	Atmospheric-like over 1<E<70 MeV energy range	20-30 $\times 10^9$ n cm <sup>-2</sup> s <sup>-1</sup> (50-100 $\mu$ A)
neutron (continuous)	Slow (moderated) neutrons depending on special applications	Flux depends on moderator system (up to 500 $\mu$ A)
proton (discrete)	Adjustable in 35-70 MeV peak; using absorbers down to $\sim 10$ MeV	(< 50 nA for pencil, < 250 nA for broad)

(\*) **F = 10<sup>9</sup>** corresponds to an integral neutron flux of  $\Phi_{E > 1\text{MeV}} \sim 6 \times 10^6$  n cm<sup>-2</sup>.s<sup>-1</sup>

### 13.1.2.2. Heat Transfer

Determines whether or not heat transfer models are applied between the sides of the interface.

The options are:

- Conservative Interface Flux**

This option enables you to define the **Thermal Contact Resistance** or **Thin Material**, which are two ways of defining the same characteristic. That is, if you do not know the contact resistance, you can define the thin material and its thickness and have the solver derive the resistance.
- Side Dependent**

#### 13.1.2.2.1. Conservative Interface Flux: Interface Model

##### 13.1.2.2.1.1. None

No models are provided for any additional heat transfer between side 1 and side 2 of the interface.

##### 13.1.2.2.1.2. Interface Model Option: Thermal Contact Resistance

Enter a numerical quantity or CEL expression that specifies the value of the thermal contact resistance from side 1 to side 2 of the interface.

##### 13.1.2.2.1.3. Interface Model Option: Thin Material

Select a material and enter a numerical quantity or CEL expression that specifies the value of the thickness of the material spanning from side 1 to side 2 of the interface.

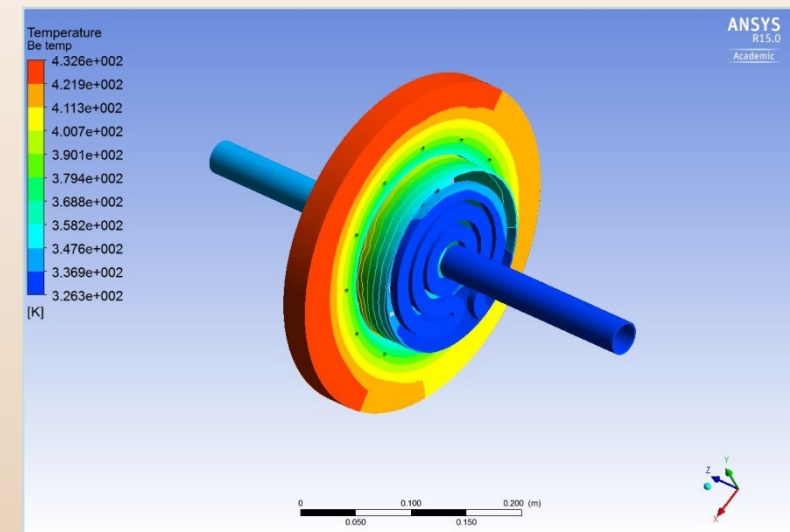

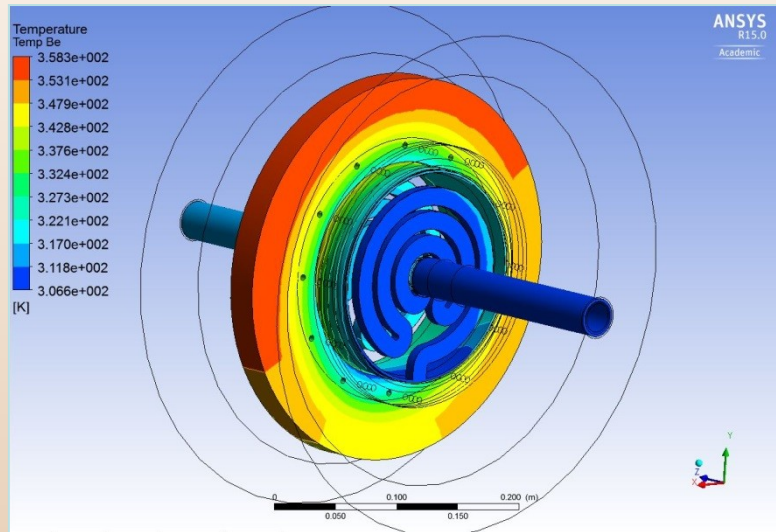

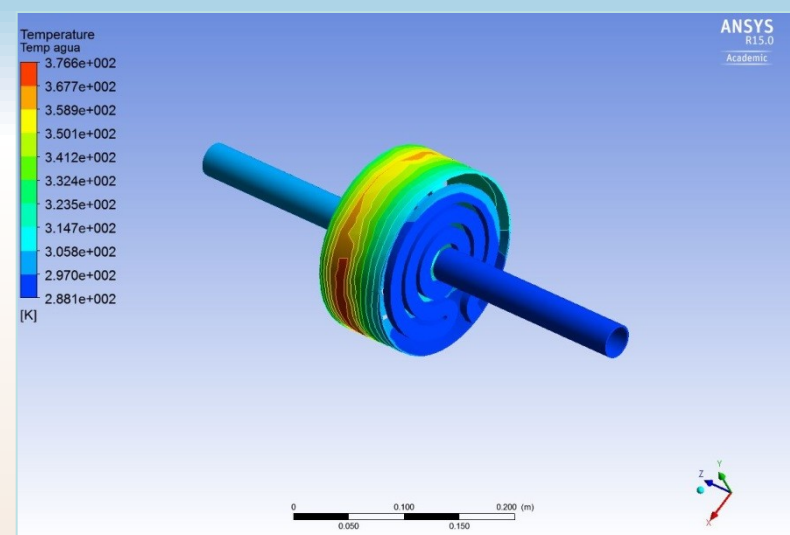

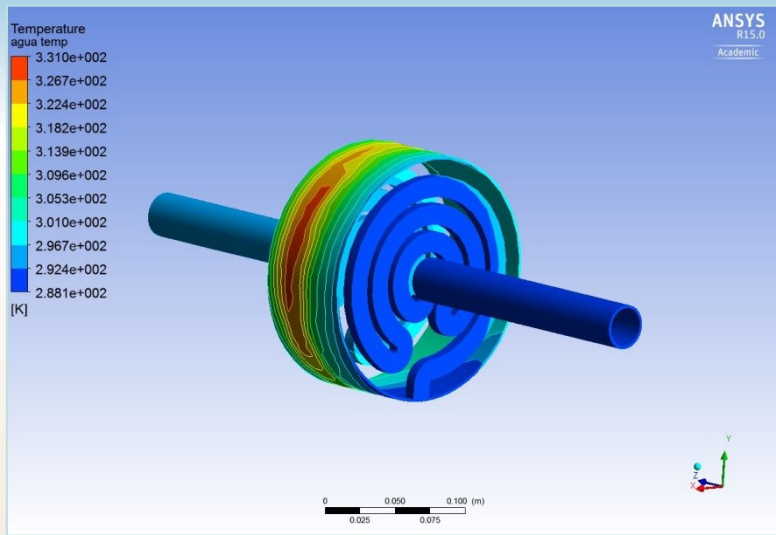

##### 13.1.2.2.2. Side Dependent

**Side Dependent** has no suboptions.

#### 13.1.2.3. Electric Field

Determines whether or not electric field models are applied between the sides of the interface.

The options are:
