Conclusions

Future work

The BondMachine: a comprehensive approach to computing.

In this presentation i will talk about:

- ▶ Ideas that bring to the BondMachine.
- ▶ What is it.
- ▶ Developed software tools.
- ▶ Hardware implementation.
- ▶ Uses.

Today's computer architecture are:

- ▶ **Multicore**, Two or more independent actual processing units execute multiple instructions at the same time.
 - ▶ The power is given by the **number**.
 - ▶ Parallel algorithms.
- ▶ **Heterogeneous**, processing units of different type.
 - ▶ Cell, GPU, Parallela, TPU.
 - ▶ The power is given by the **specialization**.
 - ▶ Hard to make units communicate.
 - ▶ Hard to program.
 - ▶ Hard to schedule.

Build a computing system with a decreased number of layers resulting in a minor gap between HW and SW but keeping an user friendly way of programming it.

Introducing the BondMachine (BM)

May 23, 2017

Mirko Mariotti

Inspired from both the ideas we create a new computer architecture that:

- ▶ Is composed by many, possibly hundreds, computing cores.
- ▶ Has very small cores and not necessarily of the same type (different ISA and ABI).
- ▶ Has a not fixed way of interconnecting cores.
- ▶ May have some elements shared among cores (for example channels and shared memories).

Connecting Processor (CP)

The computational unit of the BM

The atomic computational unit of a BM is the “connecting processor” (CP) and has:

- ▶ Some general purpose registers of size **Rsize**.
- ▶ Some I/O dedicated registers of size **Rsize**.
- ▶ A set of implemented opcodes chosen among many available.
- ▶ Dedicated ROM and RAM.
- ▶ There possible operating modes.

Shared Objects (SO)

May 23, 2017

Mirko Mariotti

Alongside CPs, BondMachines include non-computing units called “Shared Objects” (SO).

Examples of their purposes are:

- ▶ Data storage (Memories).
- ▶ Message passing.
- ▶ CP synchronization.

A single SO can be shared among different CPs. To use it CPs have special instructions (opcodes) oriented to the specific SO.

Three kind of SO have been developed so far: the **Channel**, the **Shared Memory** and the **Barrier**.

Multicore and Heterogeneous

First idea on the BondMachine

The idea was:

Having a multi-core architecture completely heterogeneous both in cores types and interconnections.

The BondMachine may have many cores, eventually all different one another, arbitrarily interconnected and sharing non computing elements.

The complexity of programming the BondMachine architecture is managed by using a set of software tools to:

- ▶ build a specify architecture as function of the task,
- ▶ modify the created architecture,
- ▶ simulate the behavior and to check the functionality with the aim to generate the Register Transfer Level (RTL) code.

Processor Builder selects the CP specifics, assembles and disassembles, saves on disk as JSON, emulates and creates the RTL code.

BondMachine Builder connects CPs and SOs together in custom topologies, loads and saves on disk as JSON, emulates and creates the RTL code.

Operations on BondMachines can also be performed via a developed web framework

The screenshot displays the BondMachine web front-end interface. On the left is a sidebar with navigation links: BondMachine logo, Tools, Processors, Bondmachines, Examples (Spring, Ping Pong), and Projects (Test). The main area has tabs for Test, I/O and Bonds, Processors, and Shared Objects. Under 'I/O and Bonds', there are sub-tabs for Inputs Management, Outputs Management, and Bonds Management. The 'Bonds' section contains a table with columns: Index, Endpoint 1 Name, Endpoint 2 Name, and Actions. The 'New' section has a 'Select Endpoints' dropdown and a table with columns: Endpoint 1 Name and Endpoint 2 Name. The 'Layout' section shows a diagram of two processors, Processor 0 and Processor 1, connected by channels. Processor 0 has inputs (i0), outputs (p0o0), and a channel (p0ch0). Processor 1 has inputs (p1i0), outputs (p1o0), and a channel (p1ch0). The diagram shows connections between p0o0 and p1i0, p1ch0 and p0ch0, and p1o0 and a channel (ch0) which connects to p0i0.

Index	Endpoint 1 Name	Endpoint 2 Name	Actions
2	p1o0	o0	Delete bond
5	i0	p0o0	Delete bond
1	p0o0	p1i0	Delete bond

Endpoint 1 Name	Endpoint 2 Name
p0o0	p0o0
p1i0	p1o0
o0	i0

An event input file describes how BondMachines elements has to change during the simulation timespan and which are to be reported.

The simulator can produce results in the form of:

- ▶ Activity log of the BM internal.
- ▶ Graphical representation of the simulation.
- ▶ Report file with quantitative data. **Useful to construct metrics**

Activity log example:

```
[discovery]> /home/mirko/Projects/conproc/tests/asm2sim % bondmachine -register-size 8 -bondmachine-file asmtest05.json -sim -sim-in

Future work

As said BondMachines are not general purpose architectures, and to be useful have to be shaped according the specific problem.

Several methods (apart from writing in assembly and building a BondMachine from scratch) have been developed to do that:

- ▶ *bondgo*: A new type of compiler that create not only the CPs assembly but also the architecture itself.
- ▶ A set of API to create BondMachine to suit specific computational problems.
- ▶ An Evolutionary Computation framework to “grow” BondMachines according some fitness function via simulation.
- ▶ *tf2bm*: A TensorFlow to BondMachine translator.

bondgo stream processing example

```
package main

import (
    "bondgo"
)

func streamprocessor(a *[]uint8, b *[]uint8,
    c *[]uint8, gid uint8) {
    (*c)[gid] = (*a)[gid] + (*b)[gid]
}

func main() {
    a := make([]uint8, 256)
    b := make([]uint8, 256)
    c := make([]uint8, 256)

    // ... some a and b values fill

    for i := 0; i < 256; i++ {
        go streamprocessor(&a, &b, &c, uint8(i))
    }
}
```

The compilation of this example results in the creation of a 257 CPs where 256 are the stream processors executing the code in the function called *streamprocessor*, and one is the coordinating CP. Each stream processor is optimized and capable only to make additions since it is the only operation requested by the source code. The three slices created on the main function are passed by reference to the Goroutines then a shared RAM is created by the *Bondgo* compiler available to the generated CPs.

Future work

One of the most important result

The architecture creation is a part of the compilation process.

Go in hardware

Second idea on the BondMachine

The idea was:

Build a computing system with a decreased number of layers resulting in a lower HW/SW gap.

This would raise the overall performances yet keeping an user friendly way of programming.

Between HW and SW there is only the processor abstraction, no Operating System nor runtimes. Despite that programming is done at high level.

The Assembly language for the BM has been kept as independent as possible from the particular CP.

Given a specific piece of assembly code Bondgo has the ability to compute the “minimum CP” that can execute that code.

These are Building Blocks for complex BondMachines.

With these Building Blocks

Several libraries have to developed to map specific problems on BondMachines:

- ▶ **Symbond**, to handle mathematical expression.
- ▶ **Boolbond**, to map boolean expression.
- ▶ **Matrixwork**, to make matrices calculation.
- ▶ **Neuralbond**, to use neural networks.

FPGA

The RTL code for the BondMachine is written in Verilog and System Verilog, and has been tested on these devices/system:

- ▶ Digilent Basys3 - Xilinx Artix-7 - Vivado.
- ▶ Kintex7 Evaluation Board - Vivado.
- ▶ Digilent Zedboard - Xilinx Zynq 7020 - Vivado.
- ▶ Linux - Iverilog.

Within the project other firmwares have been written or tested:

- ▶ Microchip ENC28J60 Ethernet interface controller.
- ▶ Microchip ENC424J600 10/100 Base-T Ethernet interface controller.
- ▶ ESP8266 Wi-Fi chip.

A set of toolchains allow the build and the direct deploy to a target device of BondMachines.

Bondgo Toolchain example

A file `local.mk` contains references to the source code as well all the build necessities.

`make bondmachine` creates the JSON representation of the BM and assemble its code.

`make show` displays a graphical representation of the BM.

`make simulate` start a simulation.

`make videosim` create a simulation video.

`make flash` the device into the destination target.

The same logic existing among CP have been extended among different BondMachines organized in clusters.

A protocol over ethernet called *etherbond* have been created for the purpose.

FPGA based BondMachines, standard Linux Workstations, Emulated BondMachines may join an etherbond cluster and contribute to a single distributed computational problem.

Parts of the system can be redeployed without changing the problem behavior (only the performances).

Two possible uses in Physics experiments are currently being explored:

- ▶ Real time pulse shape analysis in neutron detectors.
- ▶ Test beam for space experiments (DAMPE, HERD)

Real time pulse shape analysis in neutron detectors

The operation of the new generation of high-intensity neutron sources like SNS, JSNS and European Spallation Source (ESS, Lund, Sweden), now under construction, are introducing a new demand for neutron detection capabilities.

These demands yield to the need for new data collection procedures and new technology based on solid state Si devices.

We are trying to use BondMachines to make the real time shape analysis in this kind of detecting devices.

Test beam for space experiments (DAMPE, HERD)

Trigger logic for test beams

In test beams, the DAQ system relies on the trigger system for data tacking (sensor signal digitization) during

- Calibration (random trigger or “off-spill” trigger)
- On spill data taking

Minimum elements used for trigger system:

- Clock, pulser
- Logic gates (AND, OR,...)
- Delays

Trigger system implemented using NIM crates and DAQ machines

Future work

The BondMachine is a new kind of computing device made possible in practice only by the emerging of new re-programmable hardware technologies such as FPGA.

Keeping the register machine abstraction it is possible to borrow well known languages and techniques in programming these devices removing the need of having a general purpose architecture.

The result of this process is the construction of a computer architecture that is not anymore a static constraint where computing occurs but its creation becomes a part of the computing process, gaining computing power and flexibility.

Over this abstraction is it possible to create a full computing Ecosystem.

- ▶ The project is a prototype.
- ▶ Include new processor shared objects and currently unsupported opcodes.
- ▶ Extend the compiler to include more data structures.
- ▶ Improve the networking with the support for wifi.
- ▶ Work on BondMachine as accelerators.
- ▶ What would an OS for BondMachines look like ?
