A diagram of a spiral galaxy, likely the Milky Way, shown from an edge-on perspective. The central region is labeled 'Bulge'. The main body of the galaxy is labeled 'Disc'. The swirling structures are labeled 'Spiral arms'. The outermost region is labeled 'Halo'. The labels are in white text on black rectangular backgrounds, with lines pointing to the corresponding parts of the galaxy. The galaxy itself is depicted with a bright yellow core and purple and blue spiral arms against a dark background with small white stars.

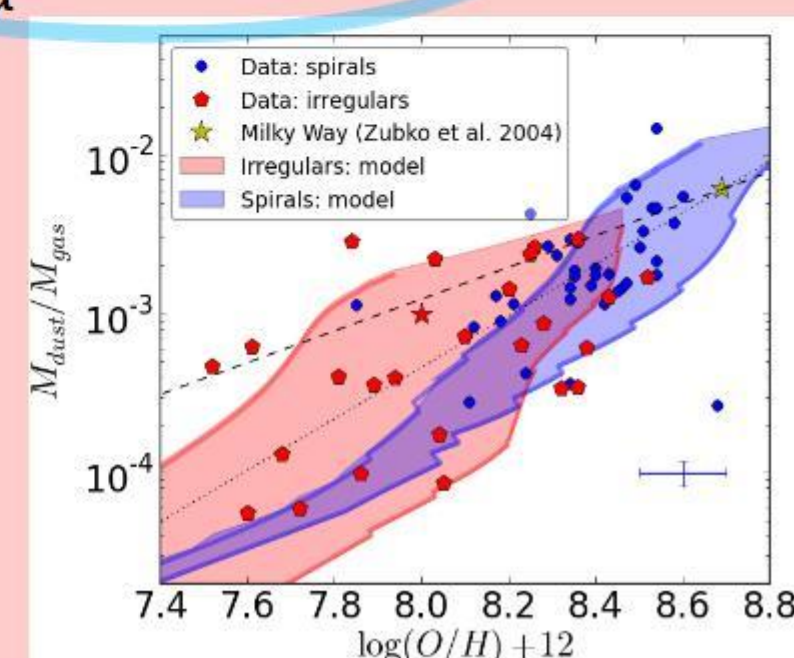

Recently, we developed a chemical evolution model which takes into account the presence of dust

We consider dust production by Type II Supernovae (SNe) and AGB stars, dust accretion and destruction in the interstellar medium (ISM), dust astration and dust-loss caused by galactic wind.

Our model is very useful to study dust properties in the ISM of different environments:

- **Elemental depletion** in Damped Lyman Alpha (DLA) systems.
- **Dust-to-gas (D/G) ratios** in the ISM of irregular and spiral galaxies (Figure).
- Investigate the **dust origin** in high redshift objects
- Study the **dust cosmic rate** across the Universe

Models for the chemical evolution of galaxies need to account for collapse of gas and metals into stars, the synthesis of new elements within these stars, and the subsequent release of metal-enriched gas as stars lose mass and die.

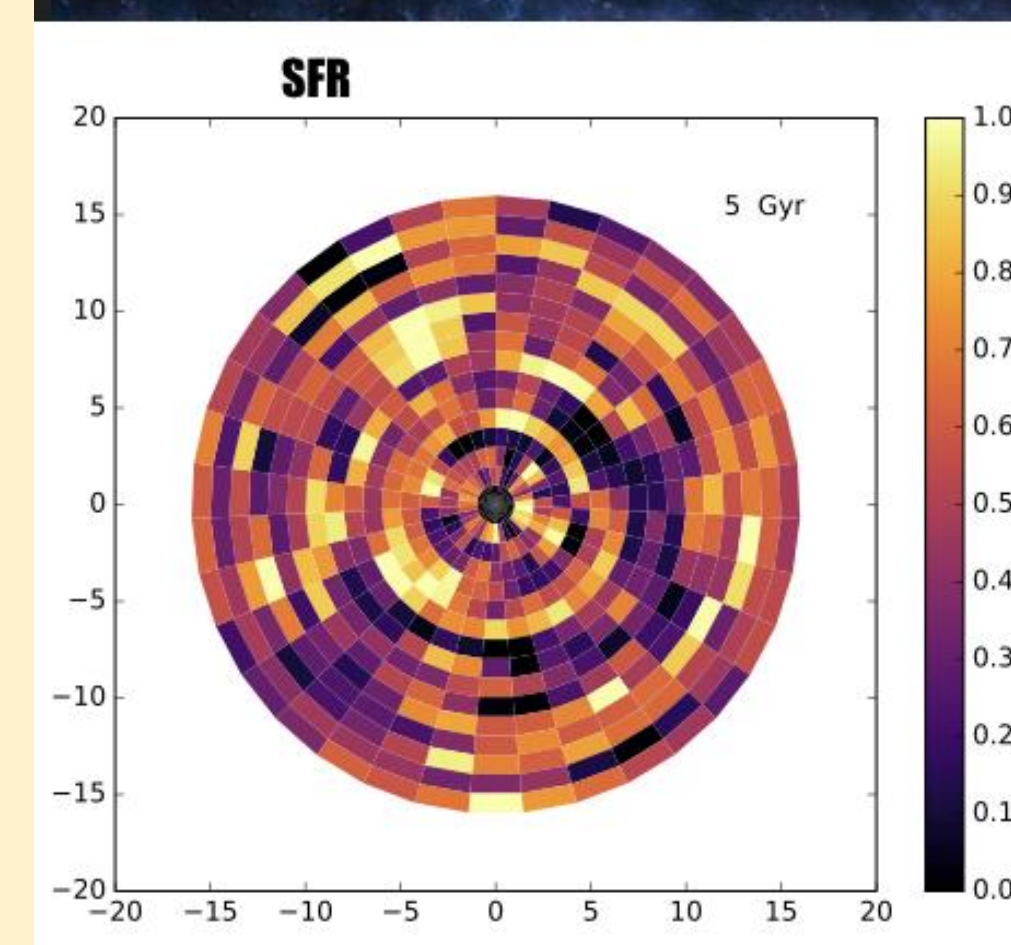

Chemo-dynamical models

Using the most advanced results of hydrodynamical simulations, we create more realistic chemical evolution models. We can now compare our results with the most recent observations of external galaxies.

Muse data of an external galaxy

THE GALACTIC HABITABLE ZONE

NUMBER OF FGK STARS WITH HABITABLE PLANETS

Y-axis labels: $3.33\text{e}+08$, $2.664\text{e}+08$, $1.998\text{e}+08$, $1.332\text{e}+08$, $6.66\text{e}+07$

X-axis labels: 4, 8, 12, 16, 20

Z-axis label: t [Gyr]

Labels on the surface: 4.3, 10.4, 7.8, 5.2, 2.6

Spitoni et al. (2017)

- ★ THE GALACTIC HABITABLE ZONE is defined as the region with sufficiently high metallicity to form planetary systems in which Earth-like planets could be born and might be capable of sustaining life, after surviving to close supernova explosion events (Gonzalez et al. 2001).
- ★ The maximum number of stars hosting habitable planets is at 8 kpc from the Galactic centre
- ★ We apply detailed chemical evolution model for the Milky Way to study the Galactic habitable zone:

Stochastic chemical evolution models

We can study the origin of the spread in chemical abundance space. In this case it is originated by two possible SNe Ia progenitors: Chandrasekhar-mass & sub-Chandrasekhar mass

The figure is a scatter plot showing the relationship between the metallicity $[Fe/H]$ (x-axis, ranging from -4.0 to -1.0) and the manganese-to-iron abundance ratio $[Mn/Fe]$ (y-axis, ranging from -1.0 to 1.0). The data points are colored according to the number of Type Ia supernovae (N_{SNIa}), with a color bar on the right ranging from 0.0 (dark purple) to -6.0 (yellow). A dashed line represents a theoretical model, and two arrows (one purple, one pink) indicate the direction of evolution. The plot shows a clear trend where $[Mn/Fe]$ increases with $[Fe/H]$, and the spread in $[Mn/Fe]$ increases at higher metallicities.

We can study the origin of the spread in chemical abundance space. In this case it is originated by two possible SNe Ia progenitors:
Chandrasekhar-mass & sub-Chandrasekhar mass
